THE MEASUREMENT OF THREAD GAGES

Description of the Instruments and Methods Used by the Bureau of Standards for the Measurement of Plug and Ring Thread Gages

By H. L. VAN KEUREN,[1] WASHINGTON, D. C.

Many of the members of this Society will recall that through the Gage Committee it was recommended that there be a central place for the certification of all master gages. The Committee further recommended that inasmuch as Congress has provided the Bureau of Standards with a fund for the certification of gages, and, furthermore, inasmuch as the Bureau of Standards was organized and prepared to handle promptly the test of all master gages, the Bureau be designated as the official place for the certification and test of gages for the various departments of the Federal Government. It is of particular interest, therefore, that the Society should know the developments that have taken place along the lines recommended, and in this connection the present paper is prepared.

MEASUREMENT OF PLUG THREAD GAGES

There are five distinct operations in the measurement of a plug thread gage, namely:

1 The measurement of pitch or lead
2 The measurement of form and angle of thread
3 The measurement of core diameter
4 The measurement of full diameter
5 The measurement of effective diameter.

Measurement of Pitch

After trying various commercial machines for measuring pitch, the machine adopted for this purpose by the Bureau of Standards was of a design similar to that of the National Physical Laboratory of Great Britain. This machine, Fig. 1, is capable of making direct measurements of pitch, and, furthermore, is not limited to any one thread interval, but determinations of the lead between any two threads may be measured. About twelve of these machines have been constructed and are in use at the various branch laboratories of the Bureau of Standards. There are incorporated in these machines special micrometer screws designed and constructed by Dr. J. A. Anderson, who is associated with Mount Wilson Solar Observatory, Pasadena, Cal. These micrometer screws are provided with aluminum heads which are graduated directly to 0.0001 in. and the screws have straight-line calibration curves to within 0.00002 in. They are therefore very well suited for the purpose for which they are used.

The operation of the Bureau of Standards pitch-measuring machine may best be explained by referring to Fig. 1 as follows: A ball-pointed stylus *A* rests in the thread to be measured. This is carried at the end of a floating arm *B* which at the other end carries a lens *C*. The arm *B* is supported by a flexible, flat steel spring *D* and the movable support upon which the spring is carried is so adjusted that the spring *D* exerts a slight pressure on the floating arm *B* which tends to cause the stylus *A* to rest firmly against the flanks of the thread. When the stylus is resting evenly on both flanks of the thread the lens *C* is directly beneath the lamp *E* and the image of the straight filament in the lamp *E* is projected by the lens *C* downward to a prism *H*, thence under the machine to the prism *I*, from where it is reflected to the screen *S*. When the image of the filament coincides with a reference line on the screen *S*, the reading of the micrometer *M* is recorded.

The turning of the micrometer head *M* causes the carriage supporting the stylus, lens, lamp, prisms and screen to move with reference to the thread, which remains stationary. Upon moving the micrometer head an amount corresponding to one thread interval the stylus comes to a position in the next thread similar to the position in the preceding thread and the micrometer head is adjusted until the image of the filament coincides with the index line as before. The micrometer reading is again recorded. The difference between the two micrometer readings indicates directly the pitch interval passed over.

Similarly each thread interval may be measured and the pitch along the entire threaded portion may be investigated. The stylus, lens, lamp, and screen form merely a sensitive optical indicator which serves to enable the pitch to be measured with a micrometer head. It is interesting to note that during the course of movement of the stylus from one

---

ANNUAL MEETING PAPERS

The thirty-ninth Annual Meeting of The American Society of Mechanical Engineers will be held in the Engineering Societies Building, New York, December 3 to 6.

The practice of previous years of having a topic of broad general interest for the leading session of the meeting will be adhered to by assigning one day for the discussion of subjects relating to Human Relations in Engineering and Industry.

Papers have been contributed by the Sub-Committees on Textiles, Industrial Buildings, Machine-Shop Practice and Gas Power. There will be a joint session with the American Society of Refrigerating Engineers, and at least two sessions for the presentation of miscellaneous technical papers.

Comprehensive abstracts of the papers to be presented are published in this number of The Journal and will be continued in the December issue. All the Annual Meeting papers appearing in The Journal are also being printed in unabridged pamphlet form for advance distribution, and members of the Society desiring a complete copy of any particular paper, previous to the meeting, may obtain it upon application to the Secretary.

Contributed discussion upon these papers is invited for presentation at the meeting and publication in The Journal and Transactions.

---

[1] Chief of Gage Section, Bureau of Standards.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

thread to the next, it climbs up over the crest of the thread and down into the next groove. During this movement the image of the lamp filament is no longer confined to the screen but the image is again brought back to the index point when the correct position in the next thread is obtained.

The optical indicating apparatus forms a convenient means of standardizing the micrometer head M. When this is done a thread gage is inserted in the machine as if it were to be tested and flat-end standards or size blocks are inserted between the micrometer spindle and ball contact against which it rests, the carriage being kept stationary and the image of

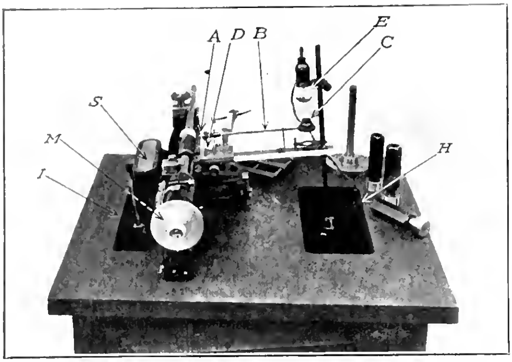

Fig. 1 Pitch-Measuring Machine Adopted by Bureau of Standards

the filament brought back to the same point with the stylus in the same thread of the thread gage at each observation.

Questions have been asked as to the result if a thread gage is not concentric with the centers. If any such indication is present the screw can be revolved 180 deg. and again tested, or it may be turned end for end in the centers of the machine. Experiments in which this procedure was taken with a large number of thread gages indicate that the difficulties of this nature are of little importance.

A still more recent development of the National Physical Laboratory is shown in a pitch-measuring machine similar in principle to the one just described, but which makes use of a mechanical indicator permitting the machine to be operated in strong daylight, whereas the optical indicator requires a subdued light or a shade around the ground glass. The micrometer-head arrangement in this machine permits the lead error to be read directly.

Measurement of Form and Angle of Thread

In the measurement of thread form or thread angle various methods such as those employing microscopic devices, conical test points, and other forms of angular test pieces used in connection with visual inspection, have been investigated and tried out, but practically all of these devices have been discarded in favor of the projection lantern. A general idea of the arrangement used at the Bureau of Standards for the projection lantern may be obtained from Fig. 2.

The operation of the projection lantern involves the placing of the thread to be examined in a beam of parallel light and, by means of a suitable lens system, the projection of the shadow of the thread on a distant screen. In the apparatus shown in Fig. 2, the light from a 10-ampere arc enclosed in housing L is emitted through the condensing lens A and directed toward the projecting lenses B and C. The screw is placed at the focus of the lenses B and C. The projection is then directed upward by a prism G to a mirror (not shown) which is supported about 10 ft. above the prism on the column K. The projection is then directed down by the mirror to the top of stage N which forms the screen and carries the standard angle M used in the examination of the thread form. As it is necessary that the parallel beam of light pass through the thread at the helix angle so that the shadow cast will be a true cross-section of the thread form, the lamp housing which carries the condensing lens A is pivoted about a point beneath the lens B. This insures that the beam of parallel light emerging from the lens A will always be directed at and fill the lens B.

Adjustments for Examinatien. The setting up of a thread gage for examination requires but a slight amount of adjustment. The stand E is provided with a motion for raising and lowering the thread, a motion for focusing the thread, and another motion for moving it along its axis in order that various portions of the thread may be brought into the center of the screen. The screw to be examined is supported by the spring centers which are carried on the stand E. For convenience in making observations it is raised until the center of the beam of light is passing the under side of the thread. The lamp L is then turned about the axis of its support until the parallel rays of light emerging from the lens A pass through the helix angle which occurs when the fringe pattern which is formed about the image of the screw due to imperfect focus, is symmetrical. The screw is then brought into focus by a slow-motion arrangement.

Measurement of Angle. The examination of the thread angle is conveniently made with a device shown on the table in Fig. 2. With this arrangement the standard angle M, known to be 60 deg., is supported by three columns on the revolving stage or screen N, which rests on a graduated cir-

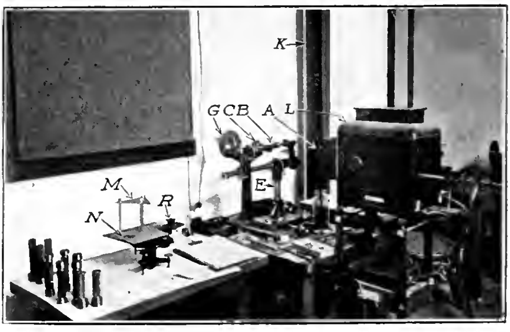

Fig. 2 Projection Lantern Used at the Bureau of Standards

cle or protractor head. In the protractor shown in Fig. 1 the graduated circle was obtained from a theodolite. During the examination of the thread angle, the opaque standard angle M is adjusted so that its shadow occupies the light space of the projected image which is cast on the surface below at N. The standard angle M is revolved so that one side exactly matches with the shadow of the thread as cast below and the reading of the graduated head is obtained through a magnifying glass. The gage is then shifted parallel to its axis by means of a slow-motion device on the stand E until the image of the other side of the thread approximately coincides with the other side of the standard angle. The standard angle is then revolved by a slow-motion screw operating the graduated circle until it again lines up with the other side of the thread, whereupon a reading of the graduated circle is again obtained.

The difference between the two readings shows directly the error of the included angle of thread if the standard angle M represents the correct thread angle.

Further application of the protractor arrangement is in the determination as to whether the thread is symmetrical about a line perpendicular to its axis. This may be verified by revolving the standard angle and matching it with the crest of the thread or by matching a straight edge which is placed perpendicular to a bisector of the standard angle with the crest of the thread.

Accuracy of the Method. It should be specially pointed out that the "shadow protractor" is an exceedingly effective device for the measurement of thread angles, much more so than any protractor, lying directly on the plane of the shadow, could be. This is because the eye is viewing two objects of similar character, namely, two shadows. When adjusting the gage for a reading, the shadows of thread and gage are made to approach and the protractor is angularly adjusted until only a faint, even thread of light remains between the two. Under these circumstances, an inaccuracy of but a few minutes is easily detected. Furthermore, the operation of the protractor is rapid. In case of particularly defective threads, exposures of the projection may be made on any photographic developing paper with an exposure time determined experimentally and a permanent record obtained of the condition of the thread.

Measurement of Core Diameter

The measurement of the core diameter of thread gages is in most cases a simple matter. It is mentioned at this point because the examination of the core diameter is generally included in the operation of investigating the thread angle and thread form while the gage is in the projection lantern previously described. It is the practice in most specifications to call for thread gages cleared or cut below the nominal flat required by the regular United States form at the root of the thread. This is done to facilitate lapping. In order to determine whether or not a gage is properly cleared when examining the projected shadow, it is only necessary to insert a suitable templet corresponding to the pitch of the screw being measured. If the projected shadow of the thread shows that it is clear below the templet form, it is passed as being correct. Fig. 3 shows a thread which has not been cleared sufficiently at the root.

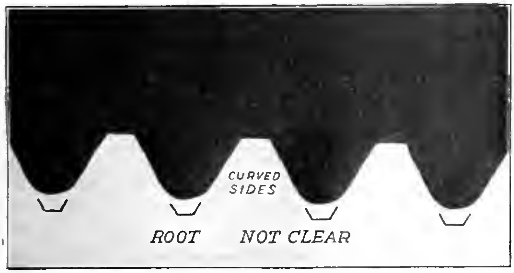

Fig. 3 Projected Shadow Showing Thread Not Cleared Sufficiently at Root

Measurement of Full Diameter

The measurement of the full diameter of plug thread gages is accomplished by the ordinary forms of flat-face micrometers or other suitable end-measuring instruments used in connection with properly authorized standards. These measurements are so simple and familiar to any one making gage inspections that no further comment will be made in this connection.

Measurement of Effective Diameter

Of the various methods which have been proposed for measuring effective diameters of male thread gages, the three-wire method is believed to be the most accurate and satisfactory. This method has been in common use for about 15 years. In measuring screws by the three-wire method, cylinders accurately ground and lapped to size and diameter are used. These wires or cylinders are inserted in the thread two on one side and one on the other. A measurement is then made directly over the tops of the wires by means of an outside micrometer or other suitable measuring device. From this measurement and from the size of the wire the effective diameter of the screw can be computed.

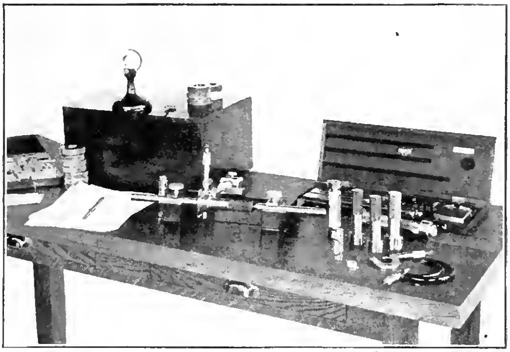

Fig. 4 Apparatus Used in Measuring Gages by the Three-Wire Method

Choice of Wires

In the choice of wires any size may be selected which will permit the wires to rest on the flanks of the thread and still project above the top of the thread. It is best, however, to choose wires of such a size that they touch the sides of the thread half-way down, or, in other words, at the mid-slope. In this case errors in the included angle of the thread have no effect on the measurement of an effective diameter. Moreover, the time spent in computations is greatly reduced. The best sizes of wire for various threads may be computed from the following approximate formula:

$$G = \frac{P}{2} \sec a$$

where G = diameter of wire, in.
P = pitch in in.
a = ½ included thread angle, deg.

For 60-deg. threads this formula reduces to

$$G = 0.5774 \times P$$

Standardization of Wires

Before the wires can be used to measure effective diameters of threads it is necessary to know accurately their diameters. The wires should be standardized in a way which approximates, as nearly as possible, the conditions under which they are used. In order to accomplish this purpose the wires are standardized with a micrometer caliper by measuring the

wire when placed over a standard reference disk, the diameter of which is accurately known. The object of measuring the wire over a cylinder is to approximate the condition of pressure which is exerted upon the wire when it is placed in the screw thread.

Computation of Effective Diameter

In the computation of the effective diameters of thread gages, if the exact conditions are recognized the formula is quite complicated and the resulting computations are very laborious. The formulæ for computing effective diameters as given in most engineering handbooks involve the use of best-size wire and do not take into account the complications introduced when considering the effects of the helix angle of the thread. These formulæ, as generally given, result in securing an answer which should check with the outside or full diameter of the screw being measured. The effective diameter is not mentioned in these formulæ and this often leads to confusion. Reference will therefore be made here to a simplified formula for 60-deg. threads which results in the direct computation of the effective diameter. This formula is as follows:

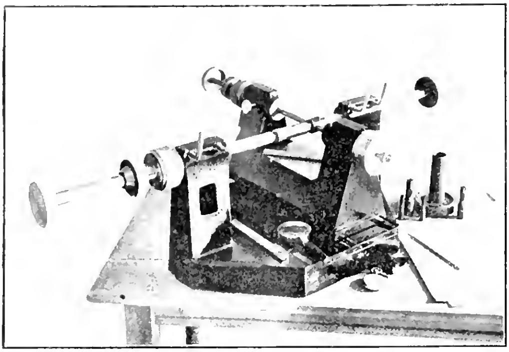

Fig. 5 Apparatus for Making Wire Measurements Using Two Wires

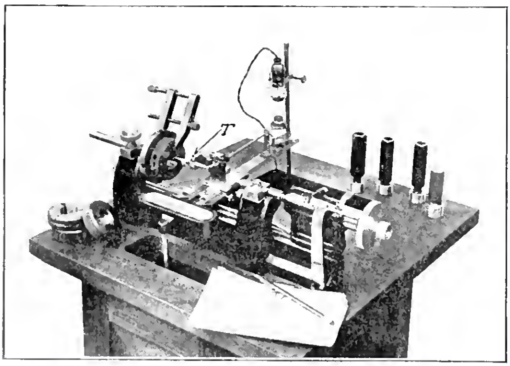

Fig. 6 Method of Measurement of Pitch or Lead of a Ring Thread Gage

$$E = M + \frac{0.8660}{N} - 3G$$

where E = effective diameter
M = measurement over the wires
N = number of threads per in.
G = diameter of wires.

In the use of this formula the term $\frac{0.8660}{N}$ may be computed for various pitches and the computations simplified. The general formula which may be used for any size of wire which will fit in the thread and which takes into account the helix angle of the thread for precision measurements, is as follows:

$$E = M + \frac{\cot a}{2N} - G\left(1 + \sqrt{\operatorname{cosec}^2 a + s^2 \cot a}\right)$$

where a = ½ the included angle of thread
G = diameter of the wires
s = tangent of the helix angle.

The above formula involves squares and square root of functions and therefore is awkward for making computations, and the following formula, which is an expanded approximation, but which is accurate to better than one hundred thousandth of an inch, is more convenient:

$$E = M + \frac{\cot a}{2N} - G\left(1 + \operatorname{cosec} a + \frac{s^2}{2}\cos a \cot a\right)$$

It should be noted that the error due to the first or simple formula rarely equals 0.0001 in., and then only when the helix angle is large.

Precautions in Making Three-Wire Measurements

It has been claimed that measurements of effective diameter made by the three-wire method result in values which are smaller than those secured by other means, such as by thread micrometers. This contention is probably justified in some cases and may be due to insufficient care in making measurements. It is important in making measurements that as little pressure as possible be applied on the wires with the measuring micrometers. Since the wires rest in a V-thread, a given pressure exerted on the top wire will have a magnified effect of distorting the wire where the contact is made on the sides of the thread. This will result in the measurement over the wires being less than it should be. Furthermore, if the wire is standardized under a light pressure and then used with a larger pressure, the diameter of the wire which is substituted in the formula for computing the effective diameter will be larger than it should be. This difference is multiplied by the factor 3 in the formula and the tendency is to make the result small. Excess pressure is often placed upon the wires during the measurement by use of ratchet or friction stops on micrometers, or by an unskilled operator, and sometimes on account of the arrangement of the wires and the screw thread when the measurements are taken. It is poor practice to support the screw being measured on two wires which are in turn supported on a horizontal surface, for if the screw is of large diameter the weight of the screw causes a distortion of the wires and interferes with the measurement.

One of the pieces of apparatus used in measuring gages by the three-wire method is shown in Fig. 4. This apparatus is known as a balanced micrometer. In operation the screw is supported between centers as shown, and the micrometer is supported on a counterbalanced arm which is in turn carried on a cylinder resting in a V-groove parallel to the centers. As originally designed, as shown in Fig. 4, the micrometer was constrained perpendicular to the axis of the thread being tested and two wires were used. The arm supporting the micrometer was overbalanced so that a slight upward pressure was given to the micrometer in order to hold a wire at the bottom of the thread and allow the operator to insert the top wire and make a reading with ease and rapidity. After using

this constrained micrometer for some time, it was found preferable to pivot the micrometer clamp on its supported arm so as to allow a slight movement in a vertical plane passed through the axis of the screw thread and then use three wires instead of two. For this arrangement two wires are carried at the bottom and one wire inserted at the top of the thread as before. This apparatus is very simple in construction and is recommended as being very convenient where a large number of gages are to be tested.

Another form of apparatus for making wire measurements using two wires is shown in Fig. 5. This instrument was specially designed and constructed for the Bureau of Standards. It embodies a precision bench micrometer accurate to within about two one hundred thousandths of an inch, supported on a heavy base and carried by steel balls. This support permits the micrometer uniform contact on the wires at either side of the thread. This machine has been found useful for threads of relatively large diameter. The instrument is of massive construction, and its rigidity, which is not common to ordinary measuring instruments, permits, when precautions are taken to avoid temperature changes, measurements which are accurate to within two or three one hundred thousandths of an inch.

TEST OF RING THREAD GAGES

The measurement of ring thread gages presents many problems owing to the difficulties with which observations may be made on the various elements. While there are various ways and means of obtaining the measurements required, it is not possible in most cases to work to the degree of accuracy that is obtainable in measuring plug thread gages. Very often the special apparatus required for such measurements is not available in commercial shops, and it then becomes necessary to judge the perfection of the ring thread by the way which it fits on a male check or checks. The various operations required for measurement are quite similar to those given for plug gages. The procedure generally embodies the following operations:

1 Measurement of pitch or lead
2 Measurement of angle and form of thread
3 Measurement of full diameter
4 Measurement of core diameter
5 Measurement of effective diameter.

Measurement of Pitch or Lead

The measurement of pitch or lead of a ring thread gage is accomplished as shown in Fig. 6. The same apparatus is employed for measuring ring threads as for measuring plug threads, with the exception that an extension stylus or attachment is provided to project into the ring and transfer the motion of the auxiliary stylus to the ball stylus used on the plug thread. This auxiliary device is shown at *T*, Fig. 6. Instead of being supported on centers, as is the case when a plug is tested, the ring is clamped on a faceplate and the operation then is exactly the same as previously explained for measuring the lead of the plug thread.

Measurement of Angle and Thread Form

The measurement of angle and thread form of ring threads is accomplished with the projection lantern in a similar manner to that employed in measuring angle and thread form of plug threads. In this instance, however, it is necessary to obtain first a cast of the thread to enable the projection to be made. The casts usually used are made of a composition of sulphur and graphite containing about 7 per cent by weight of graphite. The graphite is added to eliminate reflections which would be encountered on the surface of a plain sulphur cast in the process of projection. Then, in addition, the graphite has a tendency to reduce the shrinkage of the sulphur upon cooling. The procedure in making the cast is to clamp the ring in a vise, the jaws of which have been ground smooth, and pour melted sulphur into the ring, obtaining a cast which is a segment of a circle. The outfit required for this purpose and illustrations of the cast secured are shown in Fig. 7. The operation of pouring the casts with this method is very rapid. After the casts are poured they are immediately marked with a steel stylus with a number corresponding to the test number on the gage. The measurement of the angle is made as soon after making the cast as possible, inasmuch as experiment

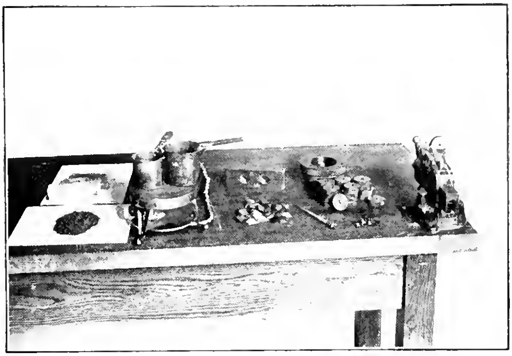

Fig. 7 Cast of Thread and Outfit Required for Making It

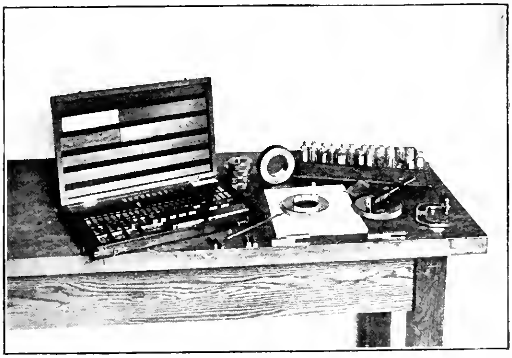

Fig. 8 Three-Ball Method of Measuring Effective Diameter of a Ring Thread Gage

shows that the cast warps but slightly during the first five or six hours, but that the warping is considerably greater if the cast is not measured at the end of 24 hours.

Measurement of Full Diameter

The measurement of full diameter is usually made part of the projection operation, as was the case of the measurement of the core diameter of plug gages. Here again it is only necessary to insert a templet in the thread to ascertain whether or not the thread has been properly cleared.

Measurement of Core Diameter

The measurement of core diameter is usually made with an

inside micrometer, Johansson inside set-up, or by the use of go and not-go plain check plugs for this diameter. This measurement of a plain inside diameter requires no further explanation.

Measurement of Effective Diameter

The method which is usually employed for measuring the effective diameter of a ring gage is by judging the fit of a gage on a plug thread check. This plug check is ordinarily ground off at the crest of the thread in order to make sure that the plug touches on the sides of the thread instead of at the crest. It is usually considered that when the ring fits snug on the plug the effective diameter of the ring is the same as that of the plug. This assumption, however, is not strictly true, inasmuch as there always is certain variation between the lead or pitch of the plug and the lead or pitch of the ring, and furthermore, variations of angle between the plug and ring are always present. Both of these variations necessitate the ring's having an effective diameter larger than the plug upon which it fits snugly. In most cases the amount actually required for fit, due to differences in pitch and angle, is appreciable, sometimes as much as several thousandths of an inch. In order to ascertain the effective diameter where check thread plugs are not available, the three-ball method of measurement has been adopted. In making these measurements the ring is laid on a flat surface with the axis of the thread perpendicular. Two balls are then placed in adjacent threads and a third ball is placed diametrically opposite. The distance between these balls is then taken by inserting size blocks together with a taper parallel, Fig. 8. The effective diameter can then be computed in a manner similar to that explained for male screw threads, as it is necessary to change only the sign of the different quantities of the formula as previously given for wire measurements. The formula as corrected for the change of sign is then as follows:

$$E = M - 0.8660 \times p + 3G$$

where E = effective diameter

M = measurement between balls

p = pitch in in.

G = diameter of balls.

This formula applies in cases where the balls used touch nearly at the mid-slope of the thread.

THE CONSERVATION OF HEAT LOSSES FROM PIPES AND BOILERS

By GLEN D. BAGLEY,[1] PITTSBURGH, PA.

The purpose of this paper is to present a more complete and detailed method of solving the problems involved in the calculation of the heat losses from bare and covered pipes and the economic problems encountered in the practical application of coverings. The factors in the economic calculations are: the cost of the heat, the cost of the covering, the size of the pipe, the temperature of the pipe, and the temperature of the atmosphere. It is necessary to consider all these factors together in order to obtain a correct result.

The data contained in the paper are a part of the results obtained in an investigation conducted for the Magnesia Association of America by the Mellon Institute of Industrial Research. The assistance received from the Association and from the Administrative Staff of the Institute has materially aided in the successful progress of the investigation, and credit is also due to Mr. G. F. Gray, who was originally in charge of the work, and to Mr. R. H. Heilman, who has assisted in securing the data.

It is generally recognized that the losses from bare pipes and boilers are considerable, but the real magnitude of these losses is little appreciated. The fact that the loss from 1000 sq. ft of exposed surface at 100 lb. per sq. in. steam pressure amounts to over 300 tons of coal annually is sufficient justification for serious consideration of the subject.

Heat Losses from Bare Surfaces

In a study of the conservation of losses, the first important fact to be considered is the actual value of the losses from bare surfaces. It is often considered that the loss from any bare surface is 3 B.t.u. per sq. ft. per hr. per deg. fahr. temperature difference between the surface and the surrounding air. While this value is correct for some special cases, it is by no means generally so. Most investigators have confined their measurements to one size of pipe at one temperature difference. Both the size of pipe and the temperature difference have an important effect on the value of this constant. Paulding in his book on Steam in Covered and Bare Pipes has worked out the theory of heat losses from bare pipes from the researches of the French physicist Péclet. The curves of Fig. 1 show the application of this theory to horizontal pipes. The solid curves indicate Paulding's values, while the dotted curves and the points give the results of various experimental tests.

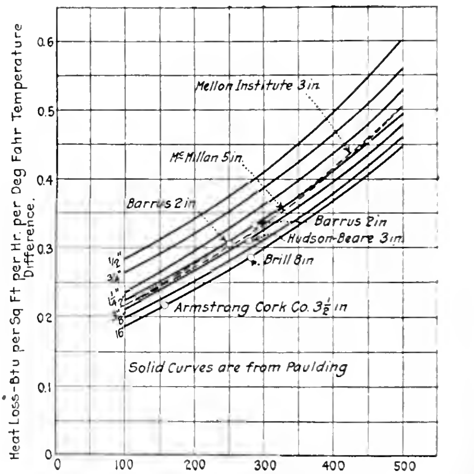

Fig. 1 Heat Loss from Bare Pipe

[1] Engineer for Mellon Institute of Industrial Research. Assoc-Mem.Am.Soc.M.E.

For presentation at the Annual Meeting of The American Society of Mechanical Engineers, New York, December 3 to 6, 1918. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

It seems that Paulding's curves give the best average values for use in calculating heat losses. They show that the constant may vary from 50 per cent below 3 B.t.u. per sq. ft. per hr. per deg. fahr. to values far above it. At 500 deg. temperature difference, which is often attained with superheated steam, the constant increases to double this value for the smallest size of pipe. In some chemical plants steam is used at temperatures of 1100 deg. fahr. The importance of using very thick insulation at these temperatures is easily judged from the rate at which the loss is increasing at 500 deg. fahr. It is to be noted that these values are all considerably higher than the values given in Kent for losses from bare surfaces.

Heat Loss from Insulated Pipes

The next important point in a consideration of the conservation of heat losses is the value of the loss after the pipes are insulated. In the apparatus used in determining these values at the Mellon Institute, the case of the heater, shown in cross-section in Fig. 2, consisted of three pieces of 3-in. pipe, the middle section being 3 ft. long and each end section $1\frac{1}{2}$ ft. long. The sections were connected by heat-insulating disks of asbestos board and each end section was provided with a hemispherical cap of cast iron. Inside of each section was an electric heater made by winding resistance wire on a frame of

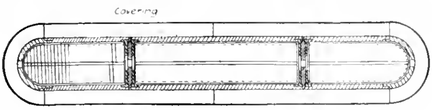

Fig. 2 Cross-Section of Heater with Covering Applied

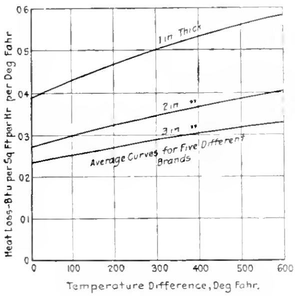

Fig. 3 Heat Loss Through 85 Per Cent Magnesia Coverings on 3-in. Pipe

asbestos boards. The wires were finely spaced and close to the inner surface of the pipe.

Results of tests made on five different makes of magnesia, in 1-in., 2-in., and 3-in. thicknesses, are shown in Fig. 3. These curves are all corrected for slight variations in thickness so that they are the true curves for the thickness given. Fig. 4 gives a comparison of the losses from a bare pipe with the losses through coverings 1 in., 2 in., and 3 in. thick. The contrast is very striking. The efficiency increases with the temperature as the loss from bare pipe increases much more rapidly in proportion than the loss from covered pipe.

Method of Conducting Tests

Two standard 3-ft. sections of pipe covering were applied as shown and the ends covered with plastic. This placed half of each section and a joint over the middle section of the heater, a condition exactly similar to actual practice. The currents in the different heaters were then adjusted until the temperatures shown by the thermocouples attached to the surface of the pipe were alike on both middle and end sections. The coverings were dried out for several days until conditions became constant, as shown by the readings which were taken every hour. The average of three consecutive constant readings was then used to calculate the conductivity. The power input was read on an accurate wattmeter and the temperature of the pipe by copper-constantan thermocouples peened into

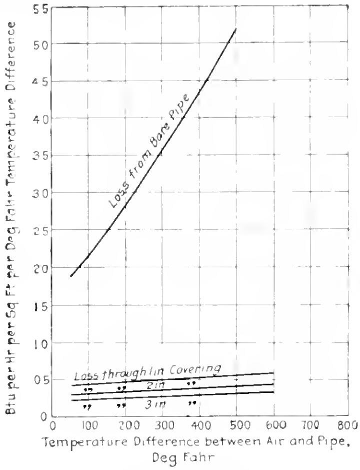

Fig. 4 Heat Losses from 3-in. Pipe with 85 Per Cent Magnesia Covering

the surface. Since the end sections of the pipe were adjusted to the same temperature as the middle, there could be no flow of heat in a direction parallel to the axis of the pipe. This obviated the necessity for any kind of end corrections in connection with the conductivity measurements. To obtain the conductivity of any covering in B.t.u. per sq. ft. per hr. per deg. fahr., it was only necessary to convert the power input to the middle section in kilowatt-hours to B.t.u. per hr. and divide by the area of the surface of the middle section in square feet, and by the temperature difference between the air and pipe. The temperature of the air was measured by thermometers suspended several feet from the pipe.

The temperature of the pipe was measured by copper-constantan thermocouples. It was found that the variation of individual samples from the standard curves of the American Chemical Society was so great that it was desirable to calibrate the thermocouples before use. This was done by the boiling-point method, which proved very satisfactory. A Siemens and Halske suspension-type millivoltmeter with a resistance of 889 ohms was used in connection with the thermocouples to measure the temperatures. This apparatus proved very satisfactory and made it possible to take a large number of readings quickly and accurately.

Calculation of Heat Losses Through Coverings

The theoretical calculation of losses through coverings on flat surfaces is quite simple, but the problem of curved surfaces is much more difficult. In this case the effect of the increased cross-section and surface area must be taken into account. Since the conductance is directly proportional to

the cross-sectional area and inversely proportional to the length of the path, it can be shown that the increment of heat loss is

$$H = \frac{2\pi K\,(T_1 - T_2)}{\log_e \frac{R_2}{R_1}} \dots\dots\dots [1]$$

where

H = heat loss in B.t.u. per hr. per ft. length of covering
T_1 = temperature of surface of pipe in deg. fahr.
T_2 = temperature of surface of insulation in deg. fahr.
R_1 = radius of pipe in in.
R_2 = outer radius of insulation in in.
K = conductivity of the insulating material in B.t.u. per sq. ft. of cross-section per in. thickness per deg. fahr. temperature difference per hr.

The loss through any pipe covering can be worked out by the use of this equation providing the value of K is known. K varies with the temperature and must be obtained from an

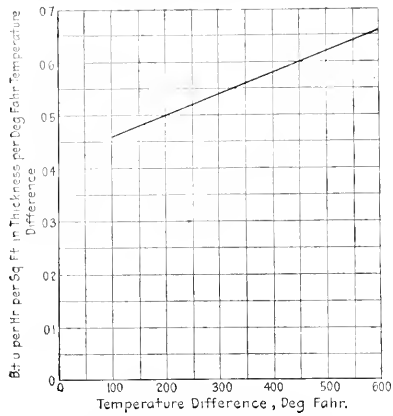

Fig. 5 Absolute Conductivity of Magnesia Plotted Against Temperature Difference at Surface of Insulation

experimental curve giving the value at different temperature differences above room temperature. The curve for K which was obtained during this research is given in Fig. 5. It should be emphasized that this kind of curve is the only fair basis for comparison of the heat-insulating value of the different kinds of coverings, as all variables due to small differences in thickness, to different sizes of pipes on which tests were made and to different surfaces or room conditions are eliminated. These curves take into account only the conduction through the material as they are based on temperature measurements at the inner and outer surfaces of the insulating material and not on the temperature at the outer surface of the canvas covering or in the air.

The difference in temperature between the outer surface of the insulating material and the temperature of the ambient air is a definite function of the heat transmitted per sq. ft. of the outer surface of the covering and of the kind of protective material used over the insulation. In Fig. 6 is given a curve showing this relation for the canvas covering as ordinarily used for this purpose. This curve was developed by L. B. McMillan at the University of Wisconsin and has been checked during this investigation. To use Formula [1] for a pipe covering in still air, an estimate of the heat loss per sq. ft. of the outer surface of the canvas covering must first be made. From the curve of Fig. 6 an estimate of the temperature beneath the canvas can then be made. Knowing this temperature and the temperature of the pipe, the term $(T_1 - T_2)$ of the formula is determined and the loss calculated. If this checks fairly well with the estimate of the loss from the outer surface, the calculation can be considered to give the proper value for the heat lost. If not, the estimated loss from the outer surface must be changed according to the indication of the calculation and the calculations repeated until the estimated and calculated losses check. This cumbersome process is necessary because of the complicated nature of the flow of heat through the compound insulation composed of the insulating material itself and the protective covering and the effect which the surface finish has on the radiation of heat from the outer surface of the covering.

In case it is desired to compute the loss per sq. ft. of pipe surface instead of per lineal ft. of covering, the formula becomes

$$H = \frac{K\,(T_1 - T_2)}{R_1 \log_e \frac{R_2}{R_1}} \dots\dots\dots [2]$$

Table 1 gives the value of the term $R_1 \log_e \frac{R_2}{R_1}$. The physical meaning of the figures in this table is the equivalent thickness on a flat surface of the given thickness on the given size of pipe. For example, a 3-in.-thick covering on a 3-in. pipe is equivalent to a covering 1.75 in. thick on a flat surface.

In connection with this work, an investigation was made to determine the distribution of temperature about a covering in still air. The results obtained show that no considerable error is made by assuming equal temperature distribution at the surface of the insulation in making the calculations.

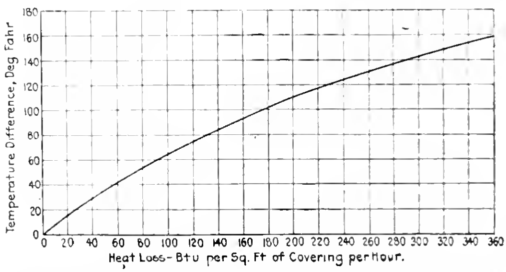

Fig. 6 Temperature Difference Between Inner Surface of Canvas Covering and Room for Different Heat Losses

Effect of Air Currents on Heat Losses

Some tests have been made and others are now in progress to determine the effect of wind velocity on the losses from bare and covered pipes. The apparatus used to determine this effect consisted of a 35-in. Sturtevant blower driven by an 8-hp. direct-current motor which furnished a blast of air for a wind tunnel. The apparatus used for testing pipe coverings was arranged inside of the tunnel so that the axis of the pipe coincided with the axis of the tunnel. This caused the air to travel parallel to the axis of the pipe and gave a condition similar to that encountered in locomotive practice.

The first test was made with a 3-in.-thick magnesia covering on the test pipe, a temperature difference of 460 deg. fahr. between the pipe and the wind, and a wind velocity of 30 m.p.h. Under this condition the loss was 0.430 B.t.u. per sq. ft. of pipe surface per deg. fahr. temperature difference

TABLE 1 EQUIVALENT THICKNESS ON A FLAT SURFACE OF VARIOUS-THICKNESS COVERINGS ON DIFFERENT-SIZED PIPES

Pipe Size, In.	Thickness of Covering, In.				
	1	2	3	4	5
3/4	0.560	0.823	0.897	1.130	1.240
1½	0.679	1.073	1.350	1.570	1.740
3	0.790	1.332	1.750	2.080	3.360
6	0.878	1.565	2.135	2.620	3.040
12	0.925	1.740	2.460	3.080	3.680
24	0.960	1.843	2.680	3.400	4.150

per hr. Under normal conditions of still air, the loss was 0.302 B.t.u. This shows an increase of about 40 per cent due to the wind velocity. From a theoretical consideration of the question, it can be shown that the maximum possible increase of loss due to wind will be reached when the temperature below the surface of the canvas covering on the magnesia is reduced to the temperature of the wind itself.

The curve of Fig. 6 shows the temperature beneath the canvas for any condition of loss in still air. When calculations are being made for exposed pipes, the loss should be calculated both by use of this curve as explained before and by using the temperature of the pipe and the temperature of the air for T_1 and T_2. By comparing the loss in still air and the maximum loss which may be caused by wind, an idea of the probable increase due to exposure can be obtained and extra thick insulation applied accordingly. Curves are being worked out to show the per cent increase in loss at various different velocities and different temperature differences.

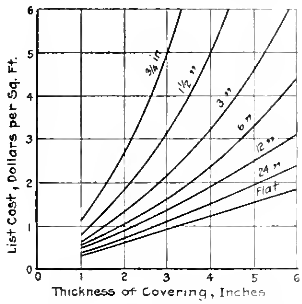

Fig. 7 Cost Curves for Different-Sized Pipes

Permanency of Insulating Qualities of Coverings

The last important point in considering pipe covering is the permanency of their insulation value. Tests were made on several old magnesia coverings. In the case of a 1-in.-thick covering which had been in service at the Armour Glue Works in Chicago for 8 years, the conductivity was found to be slightly lower than the average of the new 1-in. coverings tested, showing that no deterioration in service had taken place. Several sections were obtained which had been saturated with oil. Tests on these showed much lower insulation values than new coverings. The damage was permanent and shows that care should be used to protect coverings from oil while in service.

Initial Cost of Coverings

After considering the technical and theoretical side of heat losses from bare and covered surfaces, the next point is the economic side of the problem. In most cases the result desired is the maximum net saving of money for any given condition. If the covering cost were nothing, the proper thickness would be limited only by the requirements of space available, as each increased thickness would result in some slight increased saving in heat. In a practical case where the covering has a

inite cost, a point is soon reached where the increased cost of the covering would be greater than the additional saving in heat effected. The determining of this point is the thing in which the user of coverings is interested, as it is just at this point that the maximum net saving is accomplished.

In Fig. 7 a set of curves is given which show how the list prices of coverings vary with the thickness. By means of these curves the cost per sq. ft. of surface covered can be determined for any thickness desired. From this cost the annual fixed charges due to the covering can be calculated. After considerable investigation, it was decided that 20 per cent of the list price of the covering would be allowed as the cost of application, and 13 per cent of the total cost as the annual charges (6 per cent interest, 5 per cent depreciation and 2 per cent insurance and miscellaneous).

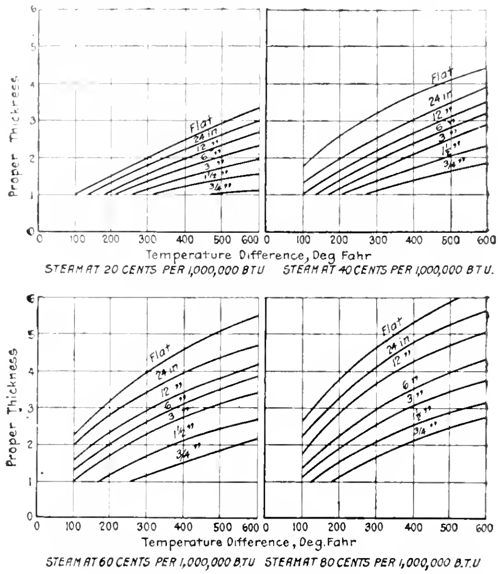

FIG. 9 THICKNESS OF 85 PER CENT MAGNESIA FOR MAXIMUM NET SAVING

OPERATING EXPENSES DUE TO HEAT LOSSES

The other cost to be charged to the operating expenses of the covering is the value of the heat losses through the different thicknesses of coverings. The previous work done on measuring the loss through 15 samples of magnesia furnished the necessary data for calculating the loss in heat units. After the heat loss was determined, it was necessary to convert the loss into dollars and cents. The assumptions used in making this conversion were that the cost of coal is 75 per cent of the cost of steam, that 1 lb. of coal as burned will evaporate 7 lb. of water from and at 212 deg. fahr., and that each pound of steam contains 1000 B.t.u. above the feedwater temperature. The value of the heat losses was calculated for seven sizes of pipes, five temperature differences between pipe and air, and four different costs of heat, both on the basis of a known cost per million B.t.u. and on a cost per ton of coal and the average conditions of steam generation given above. By making these calculations both ways, the results are applicable to plants where the steam costs are accurately known as well as to those where accurate records are not kept.

By combining the fixed cost and the heat losses per square foot per year, the total operating expenses were obtained. Once these are obtained, it is simply a matter of picking that thickness which gives the minimum annual operating expenses to obtain the proper covering to use. It is evident that the thickness which gives the minimum operating expense also

These savings are based on pipes carrying steam for 24 hours per day and 30 days per month. Coal is figured at $5 per ton, delivered.

gives the maximum net saving, as the loss from bare pipe is a constant under given conditions and the net saving is the difference between the operating expense and the loss from bare pipe.

Selection of Coverings to Give Lowest Operating Expense

The way in which the covering which gave the lowest operating expense was chosen was to plot curves of the type shown in Fig. 8 for the total operating expense for five different thicknesses. By selecting the thickness corresponding to the lowest point on each curve, the proper thickness of covering to use for the temperature difference corresponding to that curve was obtained. One set of these curves was plotted for each size of pipe at each of four different steam costs. From this set the thickness curves given in Fig. 9 were derived and from these Table 2, showing the proper thickness in relation to coal cost per ton, was obtained by making the assumption previously explained. From these curves and tables, the proper thickness to use in order to obtain the maximum net saving under any condition may easily be determined.

The saving in coal tonnage and car capacity accomplished by applying 1-in.-thick coverings to 3-in. pipe is shown in Table 3. In Table 4 the saving is expressed in dollars and cents per hundred lineal ft. of pipe per month when covered with "standard" thickness coverings and where coal costs \$5 per ton. In this case the saving varies from \$1.44 for 100 ft. of ½-in. pipe at 5 lb. pressure to \$72.40 for 100 ft. of 10-in. pipe at 200 lb. pressure and a superheat of 100 deg. fahr.

Tests of Boilers With and Without Coverings

In order that the results of the laboratory tests might be checked on a larger scale, several practical tests were made. The first and most important of these was a boiler test made in a mine plant at Bruceton, Pa., where there were two boilers of 80 and 60 hp., locomotive type, having 675 sq. ft. of exposed surface. The tests covered a period of 24 hours. Conditions of load, etc., were practically the same during both tests. During the first test while the boilers were uncovered, 10,784 lb. of coal was burned to evaporate 58,000 lb. of water. In the second test, after the boilers had been covered with 2 in. of 85 per cent magnesia blocks and plastic, 9296 lb. of coal was burned to evaporate 59,500 lb. of water, or 1500 lb. more water evaporated with 1488 lb. less of coal burned. If calculated for an equal evaporation of water, the saving in coal would be 1700 lb. per day. The calculated saving based on the laboratory experiments was between 1400 and 1500 lb. per day. This saving amounts to 15 per cent of the coal burned due to covering the boiler alone, as the pipe lines were not included in the test. (The results of this test were reported in detail at the June meeting of the A.S.M.E. at Worcester.)

It is hoped that the data here presented will be of assistance to engineers and will help in the conservation of the resources of our country.

INDUSTRIAL POWER PROBLEMS

By W. F. UHL,[1] BOSTON, MASS.

THE two principal sources of power for industrial purposes at this time are steam and water-power plants owned and operated by the industry, the so-called isolated plant; or the purchased electric current from the public-service power companies, the so-called central plant or system.

The principal points which must be considered when provisions for a power supply for an industrial plant are to be made are reliability and cost. The relative importance of these two items is in the order stated and for many plants the last item is comparatively unimportant.

Conservation of fuel, which until recently received consideration only as a part of the cost of power, is now an important factor from a standpoint of reliability also. Within the last year it has become apparent that the important thing is to have power, no matter from what source; and within very wide limits, no matter at what cost.

Reliability

The proportionate cost of power to the total cost of the commodity produced for sale in most industrial plants is below 5 per cent; and, as already stated, reliability is of much greater importance than cost when considering the supply of power for such plants. An analysis of any power situation should therefore first consider the relative reliability of the various sources of power.

When considering reliability, our first thought is generally related to shutdowns. The loss due to complete failure of power supply, when translated into dollars per hour or other time interval, is one of the uncertain quantities which makes the question of reliability so difficult of solution. This loss is subject to determination if we make certain assumptions. For instance, if we have a plant that operates continuously, the loss due to a shutdown can be directly calculated in terms of average profit, plus idle-labor cost, plus spoiled stock in process, plus fixed charges. As most plants do not operate continuously, the time lost during shutdowns can generally be made up, at least to some extent, and the loss may be reduced to the cost of labor only if the nature of the industry is such that stock in process will not spoil.

Relative Reliability

Relative reliability is also somewhat indeterminate, but there are certain factors which have an important bearing on the subject. Ignoring the question of shortage of fuel, which it is hoped is only a temporary problem, and assuming equal reliability of plant, steam power is more reliable than water power, excepting certain noteworthy cases. The chief sources of unreliability of water powers are variability of streamflow, ice troubles and floods. In most cases water power must be supplemented to some extent by auxiliary steam or other source of power to make it equally as reliable as steam power alone.

Relative reliability as between the power obtained from the isolated plant and that obtained from a central plant or system depends upon the following principal factors: (1) Size of plant; (2) reserve capacity; (3) quality; (4) transmission.

Size of Plant. Unless the central plant is several times the size of an isolated plant of 500 kw. or greater capacity, it would be unusual to obtain greater reliability because of the factors which are generally considered as having a tendency

[1] Hydraulic Engineer. Mem.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

to promote reliability merely on account of size. Such factors are design, quality of supervision, equipment, location, etc.

The average 1000-kw. isolated plant does not receive the attention in design, supervision, etc., that the average 10,000-kw. plant receives, but it would be a mistake to assume from this that all small plants are poorly designed or supervised or that there are no 10,000-kw. plants which are not poorly designed or supervised.

Reserve Capacity. An isolated plant can be said to be thoroughly reliable if it has an installation such that any one unit, as, for instance, prime mover, boiler, pump, etc., can be idle and the plant still carry the entire load. Such a plant might consist of two complete power units, each capable of

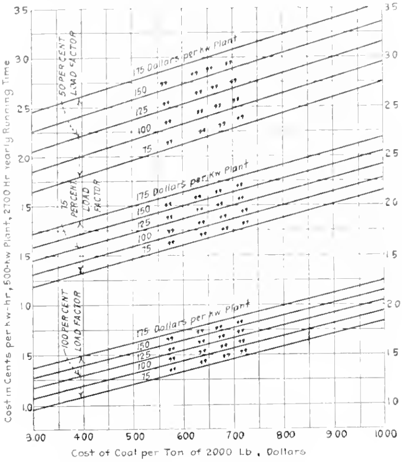

FIG. 1 APPROXIMATE COST OF STEAM POWER FROM 500-KW. ISOLATED PLANT RUNNING 2700 HR. YEARLY

carrying the entire load, and a spare boiler, or three power units, any two of which could carry the entire load if operated at some overload, and a spare boiler.

A central plant to have equal reliability as to reserve capacity must be able to carry its peak load at some overload on about 75 per cent of its rated capacity, depending to some extent on the number and size of units installed. If the isolated plant operates only nine or ten hours a day and is usually shut down over Sunday, it can get along with less reserve capacity than the central plant operating continuously, as there are more opportunities to make extensive examinations and repairs.

Quality. When speaking of quality of power, we refer to those characteristics which affect the speed and efficiency of the motors, such as speed variation and voltage regulation. These characteristics of power also affect both the quality and quantity of the product of many industries.

Speed variation is apt to be less in the average central plant, due to the larger amount of connected load and its diversity. Motors which are large compared with the total load and which carry a variable load are a source of poor speed regulation, whether connected to the isolated or central plant. Better voltage regulation is usually obtained from the isolated plant because of the absence of transmission lines.

Transmission. The one great weakness of central-plant power service is the necessary transmission. Even if the transmission is of the best and thoroughly protected by placing it in underground conduits or otherwise, it is always a source of possible trouble with which the isolated plant does not have to contend.

Under favorable conditions, this element of unreliability may be almost negligible, but more often, especially with long overhead transmission, it is the greatest source of shutdowns and poor voltage regulation in the present state of the art of power generation and use. It affects those industries most which are liable to have stock in process spoiled, due to shutdowns, or which produce a poorer grade of material on account of ununiformity.

SITUATIONS

It is possible to define a number of fairly common situations of power supply for industrial plants and to determine certain limits that it is well to keep in mind when making a comparison in which reliability, cost, conservation and policy are all considered.

An attempt is made in the following to outline a few such situations and in doing so only demands of power of 500 kw. or more are considered and these entirely in the form of electrical energy.

Situation A. An Industrial Plant Which Has No Water Power and No Demand for Exhaust Steam or Hot Water.

If a reliable central plant having several times the capacity required for the industry in question existed within reach it would ordinarily be policy to purchase power even at some increase in cost over what the power could be produced for in an isolated plant. It may be assumed that the money which must otherwise be invested in a power plant would bring addi-

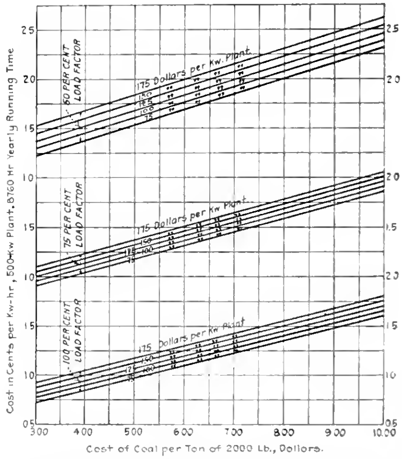

FIG. 2 APPROXIMATE COST OF STEAM POWER FROM 500-KW. ISOLATED PLANT RUNNING 8760 HR. YEARLY

tional profit to the industry if invested in manufacturing machinery, buildings or supplies. The management of the industry could be more specialized and conservation of fuel should also be a result.

The accompanying diagrams, Figs. 1 to 4, give the approximate cost of steam power from small isolated plants under various conditions and form a basis to determine the rate which

it would be policy to pay for purchased power, taking all things into consideration. The load factor in the diagrams is based on the number of hours the plant is in operation. [Additional diagram for plants up to 5000 kw. capacity are given in the complete paper, which is available in pamphlet form.—EDITOR.]

Situation B. An Industrial Plant Which Has a Water Power of Ample Capacity to Carry the Entire Load a Portion of the Time But Must Have Auxiliary Power in Some Form During Low-Water Periods and Has No Use for Exhaust Steam or Hot Water.

The cost of the auxiliary power other than cost of fuel and plant depends largely upon the following:

a Extreme-minimum stream flow, which determines the size of auxiliary plant required.

b Variation of stream flow throughout the year, which determines the number of times the auxiliary plant must be started.

c Pondage available, which determines the uniformity of demand on the auxiliary plant when in operation and the amount of banking of fires.

d Completeness of water-power development, which determines the proportion of the total load to be obtained from the auxiliary plant.

e Proximity of water power to auxiliary plant, which determines the cost of attendance.

Situation C. An Industrial Plant Which Has a Small Water Power, of Insufficient Capacity to Carry the Entire Load at Any Time, and Has No Use for Either Exhaust Steam or Hot Water.

Many industries were started at a time when steam power

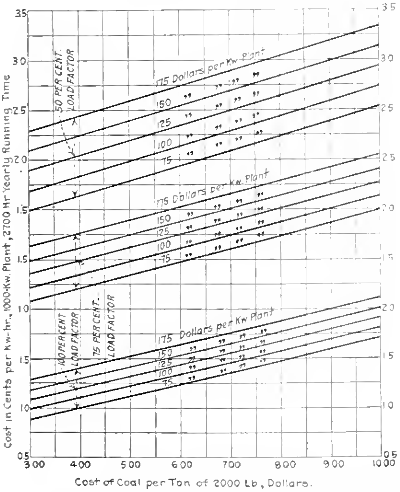

FIG. 3 APPROXIMATE COST OF STEAM POWER FROM 1000-KW. ISOLATED PLANT RUNNING 2700 HR. YEARLY

was inefficient and costly and when the demand for large and constant sources of power was not so important as at present. This naturally led them to locate where water power could be developed at small cost and which would serve all their purposes for the time being. Most of these industries which proved successful soon required larger and more constant sources of power than could be obtained from their local water power, and in many cases the water power soon became a very small portion of the total power required. Very few of these small water powers were abandoned where the industry itself prospered, although in many cases they would be found to operate at a loss if all proper charges were made against them. With others the use of water for condensing and manufacturing purposes required the maintenance of dams, ponds and other structures, which made it possible to consider a large portion or all of the fixed charges against such structures as properly chargeable to other parts of the industry than water power, thus again making the water power a profitable source of power.

Electrical transmission of power has made it possible to

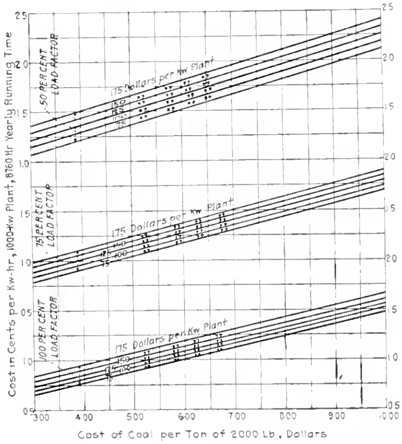

FIG. 4 APPROXIMATE COST OF STEAM POWER FROM 1000-KW. ISOLATED PLANT RUNNING 8760 HR. YEARLY

utilize many of these small water powers more fully, and in some industries where there often is necessity for overtime, night and Sunday work in some departments a small water power is valuable to carry such loads when it would otherwise have to be carried by a steam plant at inefficient part load and at considerable cost in attendance.

Such water powers may be the means of completing stock in process at a vital time, or of filling valuable orders, or keeping together at least a small part of an organization when other sources of power fail.

Unfortunately, measured in the light of improvement in the art of hydroelectric development in recent years, most of the existing small water powers and many larger ones are extremely inefficient. One of the greatest sources of fuel conservation exists in the redevelopment of water powers electrically and efficiently. Twenty to thirty per cent more power can frequently be obtained from the same amount of water and to this must be added the saving due to electrical transmission and the saving in wasted water on account of the more flexible use of the power.

It is evident from the foregoing that the value of these small water powers can no longer be determined from a purely investment standpoint, in which the cost of a certain number of kilowatt-hours produced by the water or by water and steam is compared with the cost of obtaining the same number of kilowatt-hours from a straight steam plant or from purchased power. The problem is more complex and must include power reliability and fuel conservation.

The cost of the power required by an industry other than

that obtained from its own water power in a situation of this kind is largely governed by the same limitations that have been mentioned under the previous situation. If such additional power is obtained from a steam plant, supplementary to the water power or to which the water power may be supple-

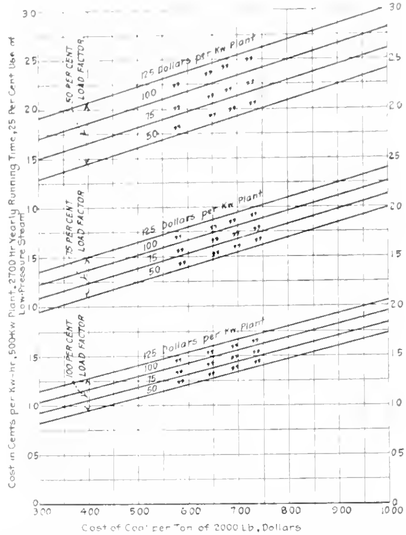

FIG. 5 APPROXIMATE COST OF STEAM POWER FROM 500-KW. PLANT RUNNING 2700 HR. YEARLY AND USING 25 PER CENT OF THE LOW-PRESSURE STEAM AVAILABLE

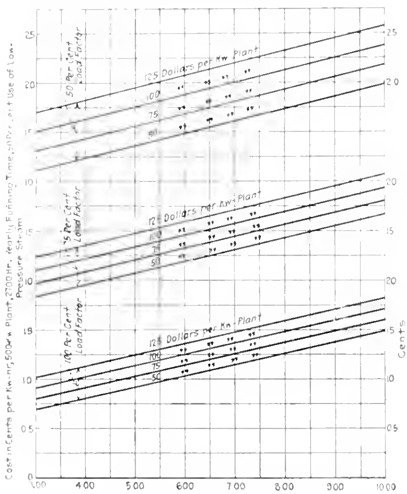

FIG. 6 APPROXIMATE COST OF STEAM POWER FROM 500-KW. PLANT RUNNING 2700 HR. YEARLY AND USING 50 PER CENT OF THE LOW-PRESSURE STEAM AVAILABLE

mentary, the size of the steam plant depends upon the extreme minimum water power available. The load factor on the steam plant depends upon the amount of water power available and to some extent upon the use made of it. Pondage, if wisely used, will decrease the size of the steam plant required and increase the load factor under which it operates.

There is a large field for fuel conservation in connection with water powers, attached to industries which operate for only 2700 to 3000 hr. annually. Either reciprocal relations should be worked out between such plants and central plants or the central plants should lease the water powers and furnish the lessor with the power required at a proper cost. The lessor could furnish the attendance at very small cost in most cases.

Situation D. An Industrial Plant Which Requires All or More than All of the Heat Which Can Be Made Available from a Steam-Power Plant in the Form of Either Low-Pressure Steam or Hot Water or Both.

Occasionally an industry is found where conditions are such, or the processes of manufacture can be arranged to be such, that the practicable supply of low-pressure steam can all be used. The demand need not necessarily be the same as the supply as long as it is always larger, as the additional supply can easily be obtained from the boilers by means of an automatic differential reducing valve connected in between the high- and low-pressure steam mains.

As nearly all industries require some high-pressure steam for certain processes, all steam is generally made at high pressure and the pressure reduced by means of reducing valves. It is evident that the steam-power cost in such a case may be comparable to the cost of water power obtained from a plant where there are no water charges, provided the first cost of the plant is about the same. It should be noted that the cost of the steam-producing part of the steam-power plant in such a case is not chargeable to power, as it would be required in any case.

Situation E. An Industrial Plant Which Can Use Only a Portion of the Heat Which Could Be Made Available if All Power Required Were Made By a Steam-Power Plant.

This is a common situation. Very often the total heat required for manufacturing purposes is in excess of that which could be made available from the prime movers, but either

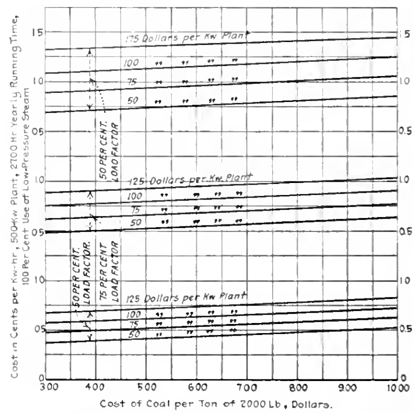

FIG. 7 APPROXIMATE COST OF STEAM POWER FROM 500-KW. PLANT RUNNING 2700 HR. YEARLY AND USING 100 PER CENT OF THE LOW-PRESSURE STEAM AVAILABLE

the demand or supply, or both, are variable and the situation cannot be developed to maximum efficiency. In other cases only a portion of the heat available is required, which may vary all the way from the plant which has use for exhaust steam only for a few months a year for building-heating purposes, which may be as low as 25 per cent of the total, to the

plant which would properly come under the preceding situation.

Many combinations of prime mover and accessories are possible to best develop a given set of conditions, among which are the following:

a Simple non-condensing engine or turbine, where the exhaust is used either entirely as low-pressure steam or partially for heating water.

b Compound condensing engine, where low-pressure steam is obtained from a receiver between the high- and low-pressure cylinders and where required hot water may be obtained from the condenser for purposes for which it may be suitable.

c Condensing steam turbine of the extraction or bleeder type, where a portion of the steam is extracted near the low-pressure end of the turbine. This low-pressure steam may be partially used to heat water or hot water may be obtained directly from the condenser. Where conditions warrant it, the condenser may be operated so that it will be really a heater rather than a condenser a great part of the time, heating water to suit the demand by varying the amount of condensing water at a sacrifice of vacuum on the turbine.

Figs. 5 to 10 are diagrams giving the approximate cost of steam power from plants of 500 kw. and 1000 kw. capacity operated under various conditions as to load factor and using 25, 50 and 100 per cent of the low-pressure steam available from the prime movers. When making comparisons between cost of power as given in these diagrams and those given in Figs. 1 to 4 for straight condensing steam plants, proper allowance should be made for the cost of that portion of the boiler plant which is not chargeable to making power.

There would be an opportunity for coal conservation as well as for financial gain in many situations of this kind, if the central plants would take over the isolated plants of such industries and tie them in with their distribution systems, operating them to the best advantage of all concerned. Efforts

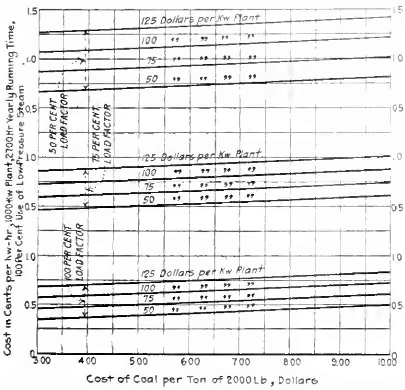

Fig. 8 Approximate Cost of Steam Power from 1000-Kw. Plant Running 2700 Hr. Yearly and Using 100 Per Cent of the Low-Pressure Steam Available

leading to such arrangements would seem to lead to better results than those which are aimed at shutting down isolated plants entirely. A common complaint coming from many industries is that they are burning nearly or quite as much coal since shutting down their steam-power plants and purchasing power as they did when running with steam.

In large industrial plants which cover much ground, the expense connected with the installation of low-pressure steam piping of sufficient size to carry the required amount of steam without excessive pressure drop and the loss of heat by radiation and condensation will sometimes be such that the use of low-pressure steam will not be warranted if it is to be supplied from a single steam plant. In such a case it is generally cheaper to use high-pressure steam for at least the

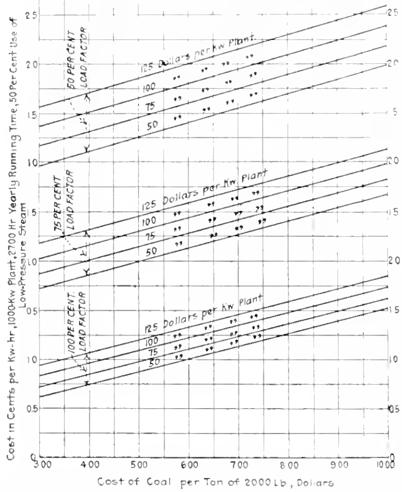

Fig. 9 Approximate Cost of Steam Power from 1000-Kw. Plant Running 2700 Hr. Yearly and Using 50 Per Cent of the Low-Pressure Steam Available

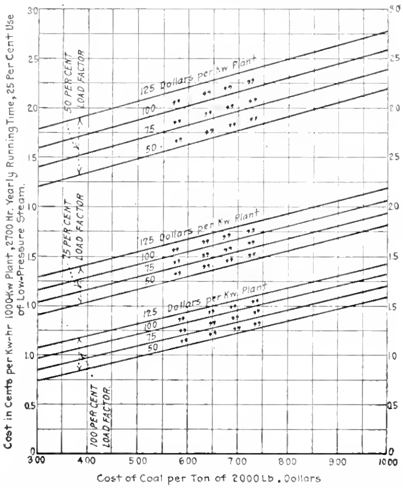

Fig. 10 Approximate Cost of Steam Power from 1000-Kw. Plant Running 2700 Hr. Yearly and Using 25 Per Cent of the Low-Pressure Steam Available

more remote parts of the industry and sometimes for all and obtain the power required from a plant operating as a straight condensing plant or by purchase from a central plant.

Situation F. An Industrial Plant Which Has a Water Power of Ample Capacity to Carry the Entire Load a Portion of the Time, But Must Have Auxiliary Power in Some Form During Low-Water Periods and Could Use All

Heat Which Would Be Available from a Steam-Power Plant.

To the cost of the water-power development must be added the cost of the necessary auxiliary plant to carry a portion of the load during low-water periods, ice troubles, backwater, etc. The cost of the power is then the total of the fixed charges, attendance and supplies for both the water power and auxiliary plant, plus the net cost of the power produced by the auxiliary plant. The size of the auxiliary plant and the extent of its output would depend upon the factors already discussed under Situation B. The only conservation of fuel would result from the difference in saving in the 10 to 20 per cent heat loss by radiation in producing the by-product steam power from the continuously operating steam plant and the auxiliary plant. The problem under this situation is generally to arrive at the cost of investment which would be warranted to develop a water power.

Situation G. An Industrial Plant Which Has a Water Power of Ample Capacity to Carry the Entire Load a Portion of the Time, But Must Have Auxiliary Power in Some Form During Low-Water Periods and Could Use Only a Portion of the Heat Which Would Be Available from a Steam-Power Plant.

This situation presents practically the same problem as the preceding one. The expenditure on water power which could be made to arrive at the same yearly cost of power as that made with a steam plant alone, would depend upon the extent of use of low-pressure steam and hot water and the auxiliary plant cost and power required from it.

In the case of large industries where the distribution of low-pressure steam is expensive, the auxiliary plant can sometimes be located near the point of greatest use of low-pressure steam and the balance of manufacturing and heating steam distributed at high pressure. Hot water can more easily be distributed over large areas than low-pressure steam. Very often the question of condensing-water supply and coal delivery will dictate the location of the auxiliary plant, with the result that all manufacturing and heating steam is distributed at high pressure.

Situation H. An Industrial Plant Which Has a Small Water Power, of Insufficient Capacity to Carry the Entire Load at Any Time, and Which Would Have Use for All Heat Made Available By a Steam-Power Plant at All Times.

Most small water powers operating under the above conditions would show a loss if all proper charges were made against them. The probability of making a water power of this kind pay for itself lies in its possible operation for overtime work and in carrying a part of the load in case of breakdown of the steam plant or in case of shortage of fuel.

A pond of some size and electrical development increase the possibilities of advantageous use of such small water powers under the above situation.

Conservation of fuel would result from the use of the water power for overtime work, if the steam plant could be completely shut down during such times.

Conclusions

Reliability of power supply is of much greater importance to the average industry than the cost of power. If the cost of power were doubled, it would be hardly noticed on the balance sheet of many industries, but shutdowns and speed drop or variation of speed may make a decided difference.

Cost and reliability being nearly equal, it would ordinarily be policy to purchase power where available. If the central plant from which the power is purchased is relatively large and has a fair load factor, this would tend toward fuel conservation.

Where an industry requires considerable heat for manufacturing and heating purposes, power can generally be made cheaper than it can be purchased, and fuel would also be saved by making rather than purchasing power in such a case.

Water power owned by an industry in many cases bears the same relation to it as does purchased power. If it is located at the industry it is often a form of reliability insurance to maintain a water power, even if there is no apparent saving due to its use.

Water powers that save coal should be maintained in any case, and there is a splendid opportunity to save fuel by redevelopment of inefficient water powers.

There exists a field for fuel conservation and financial gain for both central plant and industry, in the possibility of isolated-plant operation by the former.

In the case of water powers owned by industries running only eight to nine hours a day, the saving is of decided importance.

Under certain conditions the saving which would result from central-plant operation of isolated steam plants is also considerable.

FACTORY STAIRS AND STAIRWAYS

By G. L. H. ARNOLD,[1] NEW YORK, N. Y.

In the multi-story factory, the stairway is a detail worth much more than passing notice. Bear in mind that the people above the first floor are dependent on the stairs for egress; that four times daily the stairs are crowded by people in a hurry; that a large percentage of the minor accidents, many of the serious ones, and many panics happen on the stairs.

A poorly designed stairway may be an effective way to spread fires, smoke or false alarms and is sure to be a disturber of the heating system. A properly designed and located stairway affords not only a safe and convenient means of entrance and exit but also the handiest and most effective vantage point from which to fight fires on the upper floors.

In solving the stairway problem, consideration must be given

Fig. 1 Safety Steel Tread with Lead Plugs

to: (1) number; (2) location; (3) size; (4) type; (5) materials; (6) safety treads; (7) proportions; (8) landings; (9) handrails; (10) enclosures; (11) lighting; (12) wear.

1 Number

Where building codes are in force, the minimum number of stairways permitted is usually ample. Perhaps the most usual

[1] Mechanical Engineer, 37 Wall St., Mem.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

code requirements are one stairway plus one for each 5,000 sq. ft. of lot area.

In cases where the code provision is insufficient, and where there is no code, it is essential to consider: (*a*) safety; (*b*) capacity; (*c*) convenience.

Safety. No building over two stories in height is safe with less than two stairways. A single stairway may, at a critical moment, be blocked by a temporary disarrangement of stock or fixtures on the floor, by repairs or by a fire.

Large floors require an increased number of stairs even if but few people occupy the floor. As the distance of the extreme point from the stairway increases, so do the chances of floor barricades. Furthermore, in case of panic, fire or other accident, the time required to walk or carry an injured or fainting person 100 ft. or more may be enough to produce serious results.

Two 4-ft. stairways for buildings having up to 20,000 sq. ft. of floor area, with one additional 4-ft. stair for each additional 10,000 sq. ft., is the least number that it is prudent to use.

If the building is liable to be used for purposes which may permit the occupants to be closely spaced, the number should be increased to two for the first 12,000 sq. ft. plus one for each additional 6,000 sq. ft.

At least one and preferably all of the stairways should be carried to the roof.

Capacity. In densely populated buildings the number of stairways must be increased to prevent dangerous overcrowding when all the occupants try to leave at once. In such cases, 20 in. in width for each one hundred persons, the Boston rule for theater exits, is high, and 10 to 14 in. would be ample.

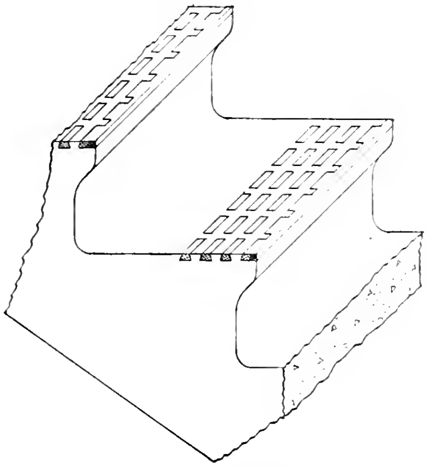

Fig. 2 Lead Safety Tread in Concrete Stairs

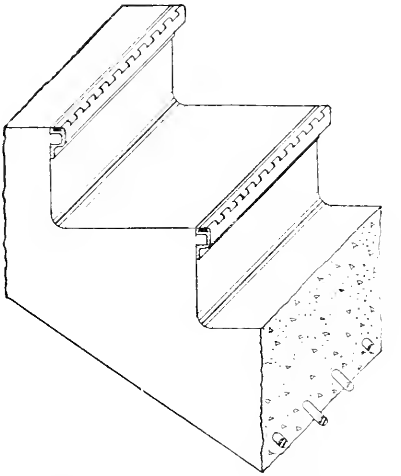

Fig. 4 Abrasive Safety Nosing for Concrete Stairs

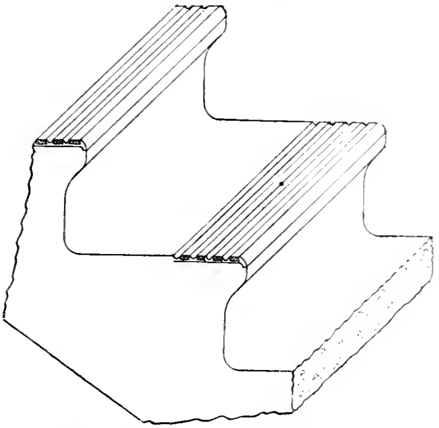

Fig. 3 Lead Safety Tread in Concrete Stairs

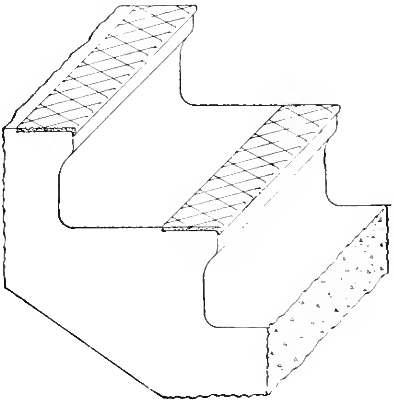

Fig. 5 Alundum or Carborundum Safety Tread

Convenience. Avoiding the disturbance of discipline and the loss of time caused by the passage of people through other departments, especial arrangements on one or more floors, the need of accommodating the building to the shape of the plot, the location of exits, and the advantageous subdivision of floors among different tenants or among different departments of the same tenant, may make it desirable to increase the number.

No question of convenience should be permitted to cause stairs to be so located that any occupant of a factory would be obliged to travel over 100 ft. to reach an exit.

2 Location

In the matter of location, many items should be considered. Every stairway should communicate directly with an exit from the building. The stairs should be distributed with a fair degree of uniformity and so placed as to reduce as much as possible the maximum distance to be traversed to reach an exit.

On each floor the landing should be so placed that lines of men going from shop to locker room, locker room to stairs, and shop to stairs, should not conflict.

It is also highly desirable to avoid obstructing the foreman's view of the room. When practicable, the separate tower or wing is the most satisfactory location. The locker and toilet rooms and the elevator can be in the tower, thus leaving the main building clear of obstructions and giving the foreman an unobstructed view of the room and permitting greater freedom in the floor layout.

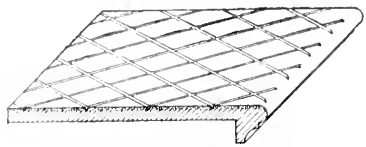

Fig. 6 Abrasive Safety Tread

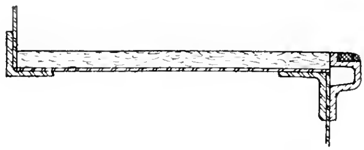

Fig. 7 Nosing for Cork Tread

3 Size

A clear width of 44 in. to 48 in. between handrails will allow the passage of two lines of people at once and the main stairs should never be less than this. If wider, the width should be in multiples of 22 in. to 24 in., the number of handrails being such that it is never less than 44 in. nor more than 48 in. between rails.

Where the number of employees is large, it is better to increase the number of 4-ft. stairs than to increase the width. Even when the number of employees in a building is large, only one floor, as a general thing, will be densely populated. This crowded floor is as likely to be at the top as at the bottom. Therefore, it is the usual practice to make factory stairways of constant width throughout their entire length.

Occasionally a factory building must be designed to accommodate dense population on two or more floors. In this case the employees from the upper floors coming down at the full capacity of the stairways will find the lower flights already taxed to the utmost and serious congestion will result. The remedy is increased widths for the lower flights.

Additional stairways from the lower crowded floors may not cure the trouble because, in the excitement of an emergency, when free and quick egress is most important, the occupants of the lower floors are likely to rush to the busiest stairway and leave their own special exit unused.

Special stairs, not used for general ingress and egress, may be as narrow as 20 in. in clear width; they may be steep, or, if not much used, they may have winders or be spiral.

4 Type

Except for special cases used by but few people for intra-department shortcuts, spiral stairs and winders should never be permitted in a factory. Straight runs alone are permissible. When the story height exceeds 9 ft., the flights should be cut and intermediate landings used. The landings should be rectangular and the flights should be not less than three risers nor more than 9 ft. high.

The intermediate landing is of little use if the flights are in line. A turn at the landing serves to limit a fall. A 180-deg. turn has the further advantage of reducing the floor space required. In fact, the stairway of minimum floor area (barring spirals) has a landing and a 180-deg. turn every 4 ft. in its height.

5 Materials

The factory stairs are usually of wood, cast iron, steel or steel with wood tread, steel with cast-iron tread, steel with stone tread, steel with concrete tread, or reinforced concrete.

The wooden stair in multi-story factories is not good practice. It is combustible and unsanitary. In buildings of mill construction, however, especially the smaller ones when not over four stories in height, sprinkled wood may be acceptable. The wood must be smooth, closely jointed, free from beads and not less than 2 in. thick, making a slow-burning construction. It is imperative that the wooden stairs be enclosed in a fireproof well.

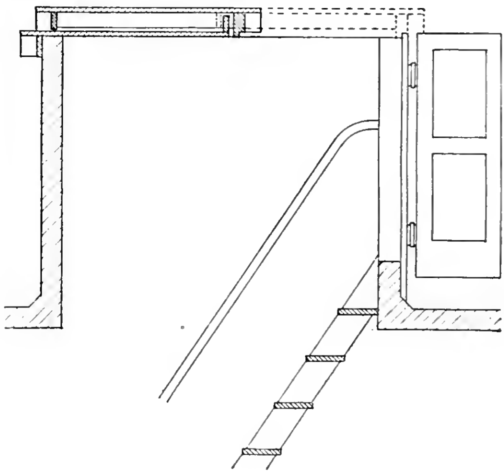

Fig. 8 Penthouse for Steep Stairs

The saving in cost, however, over a non-combustible stairway is not great enough to warrant the risk except in special cases. Cast iron and steel, while non-combustible, are not fireproof. Nevertheless, they are permissible when, as it always should be, the stairway is in a fireproof enclosure, since any fire hot enough to weaken the metals would render the stairway impassable.

Steel channels are more reliable for stringers and, except for short flights, cheaper than cast iron, and are more generally used. Risers are usually of angle and steel plate or pressed steel. Treads, while usually of cast iron, are frequently of checkered steel plate, wood, slate or concrete.

Cast iron and steel plate wear slippery and hence they are dangerous and should never be used without some sort of safety tread.

Wood, because of its inflammability, should not be used except as a safety tread over a solid sub-tread. Slate does not wear slippery but it is more expensive. It must be backed up by steel plate and replacements are expensive.

Concrete as a tread on steel stairs has no special advantage. The steel plate under tread is needed as it is for wood or slate, and to facilitate casting the steel is usually carried up to form a nosing. This is dangerous. The concrete is liable to crack off or wear below the top of the steel, leaving a lip over which, sooner or later, some one will trip and fall.

Reinforced concrete makes perhaps the most satisfactory stair if properly designed and built. There should be a good fillet between tread and riser for sanitary reasons, at least. There should be a nosing, which is not difficult to cast if made with a large fillet.

6 Safety Treads

Steel, cast iron, and concrete wear slippery and so become dangerous. Consequently, some form of safety tread must be used. Safety treads are made of: (*a*) lead; (*b*) abrasive material; (*c*) a combination of the two; (*d*) cork; (*e*) wood.

Lead Safety Tread. The lead safety tread is made by inserting plugs of lead in pockets in a steel frame, Figs. 1, 2, 3, the whole being fastened to the tread proper by screws. This of course wears more rapidly than cast iron or steel but does not become slippery and has no affinity for ice or snow. It is easily replaced when worn. The chief objections to it are that, owing to the grooves between the lead plugs, it is difficult to keep clean, and there is a chance for a heel to catch in the grooves.

Abrasive Safety Tread. The abrasive tread is made of alundum or carborundum cast into hard metal, leaving the grit projecting slightly above the surface of the metal, Figs. 5 and 6. The abrasive is also imbedded in the rounded nosing to prevent slipping on the edge of the step.

This type of safety tread is made to be used as the complete tread as well as the renewable safety tread bolted to a sub-tread. It is also made as a nosing, this form being especially useful on concrete stairs, Fig. 4.

This is probably the most durable tread in heavy traffic. It is, however, hard and noisy and, like the lead tread, it is difficult to keep entirely clean. There is also a chance that the grit may be too sharp: Instances are known where the shoe has been gripped so firmly as to cause a fall.

Combined Lead and Abrasive Safety Tread. A third type of safety tread is made of grains of abrasive in a lead matrix, the whole carried on a steel plate. It is made either grooved or flat, and with the anti-slip surface carried to the front edge.

The flat top is a great advantage as it makes it possible to keep the stairs clean. For outdoor use, it shares with the lead tread the advantage that snow or ice do not adhere. It also shares with the other type of abrasive tread the danger of too acute a grip.

With either of the above three types of tread, it is not necessary to cover the entire width of the tread. If the front edge of the step to a depth of 3 in. to 3½ in. is protected by a non-slipping surface, the remainder of the tread only needs to be brought up flush with the safety strip.

Cork Tread. Cork as a safety tread is not so well known nor so widely used as it deserves to be. It is impervious to almost all liquids and hence is easily kept in a really sanitary condition. It is noiseless, wears surprisingly well and is the pleasantest of all materials on which to walk.

Unfortunately, its lack of strength makes it necessary to use a metal or wood nosing. This is not dangerous, however, because owing to the elasticity of the cork, the nosing will wear ahead of it.

Where stairs are liable to rough usage, as by dragging heavy pieces up or down, the cork tile is sometimes used with a nosing having a lead or abrasive non-slip surface. See Fig. 7.

For use as a safety tread, the cork is compressed into tiles ½ in. thick by 9 to 12 in. sq. These are cemented to the sub-tread.

Wood Safety Tread. Except under the heaviest traffic, wood makes a splendid safety tread. Laid directly on top of a solid steel or concrete base and exposed only on the top and front edge, the fire risk is practically eliminated.

Wood offers one of the most satisfactory surfaces to step on. It is never slippery and it is cheap. The worst objection to it is from a sanitary viewpoint because it absorbs expectoration.

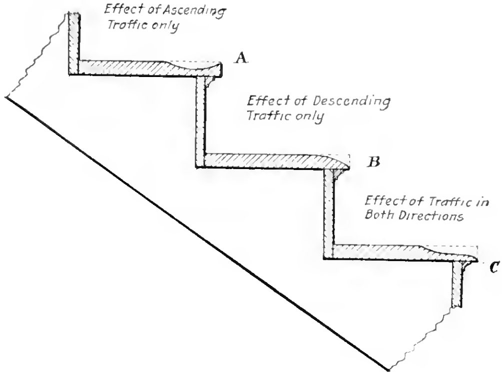

Fig. 9 Characteristic Effects of Wear on Steps

The wood should be either oak, maple or edge-grain yellow pine to wear well, the last-named being undoubtedly the longest-lived. Each tread should be made in three pieces. The rear strip will never need to be renewed and the center strip but rarely.

7 Proportions

Although the pitch of stairs must be kept within comparatively narrow limits for best results, still it is possible to make a safe and reasonably comfortable stair at almost any pitch if due regard is paid to relation of rise to length of run.

The natural length of steps decreases rapidly as the grade increases, even on a ramp where the surface offers equal foothold at all points.

Failure to take this fact into consideration results in a stair which is awkward and tiresome, with a pronounced tendency to produce stumbling and falls.

The length of the foot, or rather of the shoe, is not an important factor. For one thing, the actual length of the tread exceeds the run by the amount of the nosing. For another, practically all the work of ascending and descending stairs is done by the ball of the foot. In ascending the weight is borne on the ball of the foot in the middle of the step while the heel projects in the air. In descending, the toe projects, the weight being borne on the ball on, or just back from, the edge of the step, the heel barely touching the step.

For adults, making the length of the run plus twice the rise equal to 24 in. to 24½ in. can be relied upon to give satisfactory proportions.

By this rule, the rungs of a ladder should have a 12-in.

spacing, which is the recognized standard, and a 45-deg. stair would have an 8 in. rise and an 8 in. run, which a wide experience shows to be entirely satisfactory. A horizontal grating would have a 24 in. spacing, which, although a trifle short, is nevertheless within the bounds of practicability.

In factory practice, the tendency is to make the stairs steep in order to save room. Observation by several people over a period of years and under a wide variety of circumstances confirms the opinion that an 8-in. rise by an 8-in. run is the steepest stair practicable for general use and that $7\frac{1}{2}$-in. rise by 9 in. run is much better. Some building codes prescribe $7\frac{1}{2}$ in. as the maximum height of run. Although 7-in. rise by 10 in. run makes probably the easiest of all stairs, the improvement over $7\frac{1}{2}$ in. by 9 in. is not usually worth the extra floor space consumed.

Out-of-doors stairs or steps should be made with only 6 in. rise, if possible. In any case, the rise and run must be uniform throughout the entire length of the stairway. Otherwise, falls will be frequent.

8 Landings

All landings should be rectangular and at least as deep as the stairs are wide. The surface should be of the same material as the stair treads. Attempts to save room by cutting off corners or reducing the size of landings, or by the introduction of winders or straight steps invariably result in accidents, especially when the stairs are crowded and every one is in a hurry.

9 Handrails

Each line of people on the stairway should have a continuous, firmly supported handrail at a convenient height and of such size and shape as to be readily and securely grasped.

The material may be wood or metal. If of metal, the rail will usually be iron or occasionally brass pipe and of $1\frac{1}{2}$-in. or $1\frac{1}{4}$-in. iron-pipe size. The $1\frac{1}{4}$-in., although somewhat small, has the advantage that the fittings are more generally carried in stock. Large sizes are used but they are objectionable as they cannot be grasped securely in the frantic effort to recover from a misstep, especially by a person with small hands.

T-bars and special rolled, drawn or cast handrail sections, are frequently used but, except for the architectural effect, they have no advantage over the cheap and homely wrought-iron pipe.

If the rail is of wood, it should be of oak, ash or some other non-splintering hardwood; never yellow pine. It may be a round bar not less than $1\frac{3}{4}$ in. in diameter nor more than $2\frac{1}{4}$ in., or it may be one of the stock patterns carried by the mills.

In any case it must be strongly supported at a height of 31 to 33 in. above the front edge of the step. Around the landing, the height should be 36 in.

Open stairs require either a second rail at half height or a strong wire netting between stair and rail.

10 Enclosures

Notwithstanding the fire risk, the danger from things dropped or thrown, the chance for falls and the increased difficulty of heating, open stairways are frequently found in factories.

Every stairway should be enclosed in a fireproof well. In many cities a wire grill is permitted between stairs and elevators in the same well. A solid partition is more satisfactory and pays for the extra room and expense.

Choice of material will be governed by the same considerations as in the case of the other partitions.

The space under the bottom flight must be left open and kept clear unless filled up solid with non-combustible material.

If the stairs extend to the roof, the enclosure should be carried above the roof in the form of a bulkhead or penthouse high enough to allow a door 6 ft. 6 in. to 7 ft. in height.

If the roof flight is a ladder or a very steep stair, the penthouse may be replaced by a scuttle, or better, by a companion as shown in Fig. 8.

The door or scuttle should be hooked, latched or bolted in such a way that, at any time, it can be opened readily from the inside.

The roof of the stair well should be a skylight with a wire netting under the glass to catch pieces of glass in case of breakage.

At each story liberal wire-glass windows with metal frames should be provided so that the whole shaft shall be as light as may be in daylight. The better the illumination is, the fewer days in a year will artificial light be required.

All stairway openings should be closed with Underwriter automatic fire doors opening with the outgoing current. The outside doors need not be fire doors but should open out. Where there is much traffic, the fire doors may be supplemented by glazed double-acting doors.

The locks on all these doors should be such that under no circumstances can a person be locked in.

Care should be exercised to locate these doors so that they may be opened without risk of crowding some one off the landing and so that a stream of people descending cannot prevent them from being opened.

11 Lighting

In the artificial illumination of the shaft, brilliancy is not required but thorough distribution is. A light should be placed at each floor and each turn. The lighting should be in duplicate.

Since there is always a likelihood of a small group of employees being in the place at night after the stair lights are out, it is quite necessary to reduce to a minimum the distance one must grope in the dark. For this reason the electric lights should have double-acting switches at each end of each circuit and the emergency lights, whether gas, candle or lantern, should be so placed that each flight can be lighted on the spot.

12 Wear

Steps, subject to ascending traffic only, wear as shown in Fig. 9, at *A*. If the traffic is descending only, the wear is as at *B*. If subject to traffic in both directions, the wear will be as at *C*.

In any case, renewal of the front third of the tread will usually restore the worn step. At long intervals the middle third may have to be renewed if the traffic is very heavy.

Mr. F. A. Waldron, during the years 1896 to 1906, at the Yale & Towne Manufacturing Co., made extensive experiments on the wear of wooden treads constructed in three pieces. Hard maple, on account of its superiority for flooring, was taken as a basis of comparison. Mr. Waldron's method was to use the hard maple on every other step, putting the wood on trial on the alternate steps. Ordinary yellow pine proved to be very short-lived. Edge-grain yellow pine, on the other hand, proved to be by far the most durable, outwearing the maple two to one.

Where safety treads 3 in. or $3\frac{1}{2}$ in. wide are used, practically all the wear will come on the safety tread and only this will need renewal.

PROPERTIES OF AIRPLANE FABRICS

Methods Used by the Bureau of Standards in Developing a Cotton Fabric as a Substitute for Linen for Airplane Wing Coverings

By E. DEAN WALEN,[1] WASHINGTON, D. C.

THE early coverings of the wings of heavier-than-air machines consisted usually of a plain cotton fabric, coated with a beeswax compound or some sort of glue. Such a covering was not very strong and sagged materially when subjected to pressure or exposed to weather. It became necessary in the development of the planes to cover the wing surfaces with a material of high strength and low weight. Accordingly unbleached linen fabric, woven from yarns spun from flax, was used and found satisfactory, but the supply of linen in the present crisis would not suffice to meet the heavy demands and a search for substitutes was imperative.

Previous difficulties in experiments on cotton fabrics were four: (*a*) low strength per unit of weight; (*b*) low tearing resistance; (*c*) little shrinkage upon application of dope; (*d*) little tendency to retain what little shrinkage they had after doping.

In March 1917 the Bureau of Standards was able to issue instructions to various fine-goods cotton mills covering the construction of cotton fabrics for experimental purposes. In the early part of May 1917 a fabric had successfully passed the laboratory standards, and service tests in the field were started, with very satisfactory results, and the present Grade A cotton fabric was evolved.

In August 1917 a conference between the military authorities and representatives of the Bureau resulted in the Signal Corps Equipment Division's ordering the Bureau to supply necessary specifications for the purchase of 500,000 yd. of cotton airplane fabric.

Recently the standard fabrics were submitted to the English airplane authorities and the results of their tests were astonishingly successful. Since that time the English have adopted the standard Grade A fabric.

An interesting development in this connection was the fact that the Italians, working on the same problem at the same time, produced a fabric which had been used successfully on the battlefield and which differed but slightly from our own as far as thread count and yarn number are concerned.

Before suitable substitutes can be found, it is necessary to determine the requirements which a material must satisfy, together with the properties of the material being substituted. The following discussion treats of the methods of determining the properties of textile materials, from which may be determined their compliance with the requirements of airplane wing coverings.

Method of Covering Airplane Wings

It is thought advisable to discuss briefly the method of covering airplane wings in order that one may follow the discussion with more interest. The frame of an airplane wing is covered with a fabric according to one of the following methods: The fabric is sewed into a piece which is wide enough to cover, and is folded completely over and under, the wing frame. It is then tacked on the three open sides after being stretched just enough to take out the wrinkles. The raw edges of the fabric are then sewed together and the tacks removed. The other method consists in making a pocket of fabric and slipping it over the frame. The open end is then tacked and sewed the same as in the previous case. The system of threads in the fabric may have the following two relations to the major and minor axes of the wing: the warp running from the "leading-in" edge to the "trailing" edge, or parallel to the short or minor axis of the wing; or, it may be put on such that the warp is at 45 deg. to the axis of the wing.

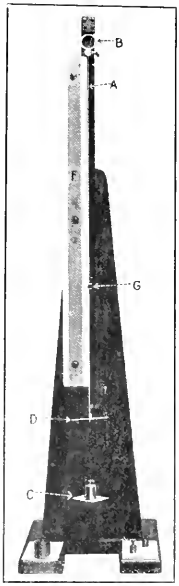

Fig. 1 Instrument for Measuring the Length of Yarn

The fabric is laced to the wing ribs at intervals of about six inches. After the fabric is on the frame, it is treated by means of a brush with a solution of cellulose acetate or nitrate with suitable stablizers, etc., which is termed "dope." The dope has the property of producing a tight drumhead-like wing covering, which is often attributed to the shrinking of the fabric. It also serves to fill in the interstices of the fabric, making a surface which has a coefficient of friction to air approximately equal to that of plate glass. The doped wing fabric may be considered as a rectangular membrane fixed at two sides and supported on the other two sides by the ribs of the frame, and that the wing is composed of many of these sections.

Determinations of the Properties of Undoped Fabrics

Moisture. The amount of moisture is found by drying the sample to a constant weight in a ventilated drying oven main-

[1] Chief of Textile Section, Bureau of Standards. Jun.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

tained at a temperature of 110 deg. cent., and expressing the difference in weight from the conditioned weight in terms of the bone-dry weight. This is commonly termed "regain."

Weight. Pieces of 4 sq. in. are cut from various parts of the sample and weighed after exposure to the standard atmosphere, the results being expressed in terms of weight per unit of area.

Length of Yarn. The length of a yarn is considered to be that length when the yarn is straight and under no tension. The yarn is stressed in tension by equal increments of load and the stretch readings are taken at any particular load when the increments of elongation per unit of time are small. The stretch is plotted against the load. It has been found that after the fibers and the yarn have adjusted themselves the load-stretch curve follows a straight line. The straight-line portion of the curve is extended to intersect the zero-load coördinate, and this length taken to be the length of the yarn when straight and under no tension.

The apparatus is shown in Fig. 1. The yarn A is clamped at one end in the clamp B. The other end supports the weight pan C. The yarn is prevented from untwisting by the cross-arm D. The clip G is an index mark to read the changes in length on the scale F.

Crimp. The crimp of a yarn is the increased length of the yarn taken from the fabric over the length of the fabric. The difference is caused by the interlacings of the yarns. This length of the yarn removed from the fabric is determined in the manner outlined above.

Yarn Count. The yarn count is a term used to designate the size of the yarn and is expressed in terms of length per unit of weight. For instance, a No. 1 cotton yarn has 840 yd. to 1 lb. It may be considered as a very approximate index to the diameter of the yarn.

Thread Count. The thread count is the number of yarns per inch of width of the fabric, and its determination needs no discussion.

Twist of the Yarns. This term is perfectly obvious and needs no discussion. It is determined by counting the turns necessary to untwist the yarn, and the result is expressed in terms of twist per unit of length of the yarn before untwisting.

Tensibility Properties. The tensibility properties of a textile material may be defined as the behavior of the material when subjected to tensile stresses acting parallel to and at the center plane or line of the material. These may be divided into the following: (*a*) load-stretch relations; (*b*) tensile strength; (*c*) restitution and hysteresis.

The tensibility properties are determined in a testing machine of the inclination-balance type arranged to plot autographically the stretch against the load. A diagrammatic sketch of the apparatus is shown in Fig. 2. The inclination balance is represented by the pendulum arm A_1 and the sector arm A_2 which are rigidly connected and pivoted at the point B. The principle is one of balanced moments and its theory needs no discussion. The load applied at D is read on the scale C.

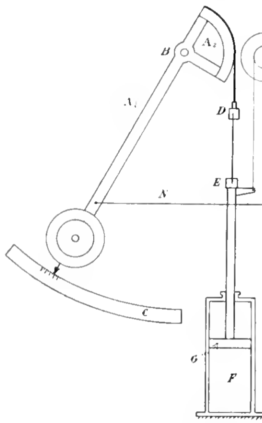

FIG. 2 INCLINATION-BALANCE MACHINE FOR TESTING TENSIBILITY PROPERTIES OF TEXTILE MATERIAL

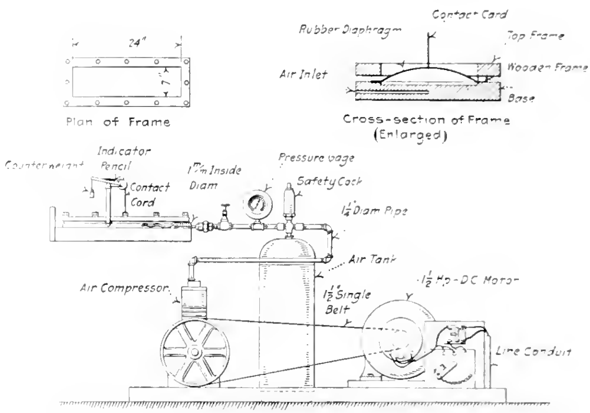

FIG. 3 APPARATUS FOR TESTING BURSTING STRENGTH OF CLOTH UNDER UNIFORMLY DISTRIBUTED PRESSURE

The fabric clamp E, which may be termed a pulling clamp, is operated up or down at will by hydraulic pressure acting on the bottom or the top of the piston G confined in the cylinder F. The motion of the balance arm revolves the drum K by means of the thin, narrow brass ribbon N. The motion of the pulling clamp moves the pen L along the vertical axis of the drum by the ribbon M and the magnifying pulley H. The pen is arranged to make a dot every second. [The paper discusses possible errors of the instrument, for which corrections were made.—EDITOR.]

The tensibility properties are determined in the following manner, which it will be noticed is a deviation from the usual method: Samples of fabric are cut 3 cm. wide by 25 cm. long. These are raveled to 2.5 cm. wide, and allowed to condition. They are then placed in the clamps of the testing machine with 20 cm. between clamps and stressed by reason of their being stretched at the rate of 13 cm. per min.

The tensile strength and load-stretch relations are taken directly from the chart.

The hysteresis and restitution properties are determined by stressing the fabric specimen to a certain load, and relieving the stress in the same manner as applying it. This may be repeated a number of times and the results taken as an index of the fatigue properties of the material.

Tearing Resistance, Tensibility Method. For this particular purpose the tearing resistance is determined in the following manner, which is a slight modification of the English method:

Specimens 25 cm. wide and 36 cm. long are clamped in the testing machine with 30 cm. between clamps. Slits are cut at the center and perpendicular to the line of pull, and the fabric is then stressed at the rate of 13 cm. per min., and the maximum load transmitted is recorded. The length of the slit is plotted against the load recorded.

The maximum length of slit which may be used with this size of sample is determined by the proximity of the zone of stress about the tearing point to the edge of the sample. The area of this zone is easily determined by drawing a series of lines parallel and perpendicular to the line of pull. These lines will be distorted in the zone of stress.

Resistance to Uniformly Distributed Pressure. The material is clamped over a rectangular container and subjected to air pressure. The apparatus is shown diagrammatically in Fig. 4.

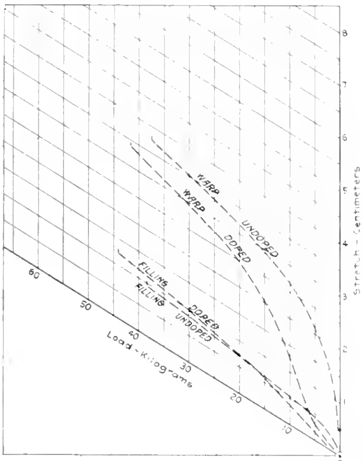

Fig. 4 Load-Stretch Relations of Standard English Grade A Airplane Linen

The deflection of the center point of the fabric is plotted against the unit pressure under the fabric by means of an ordinary steam indicator. The shape of the deflected surface is determined by measuring the vertical displacement of a series of rods placed at various points over the surface and free to move only in the vertical plane.

The rate of flow of air into the chamber under the fabric is very slow and is regulated by passing the air which is under a pressure of 10 kg. per sq. cm. through 110 cm. of 1-mm. tubing. A sheet of rubber dam is placed under the fabric to prevent air leakage. Considering these precautions, it is reasonable to assume that there is a very uniform distribution of pressure under the fabric. As there is practically a zero rate of flow of air into the indicator, it is reasonable to assume that there is no pressure drop in the connecting line.

In the surface formed by plotting the load-stretch and time relations of a fabric, there is a region where a change in the rate of load application produces only a slight change in the tensibility properties of the material. The rate of load application in this apparatus is adjusted by the definition of the pressure and dimensions of the capillary tube in such a manner that the variations in the load application produce only a very slight difference in the recorded tensibility properties of the material.

Bursting-Tear Test. The procedure is similar to that followed in the determination of the resistance to uniformly distributed pressure excepting that slits are cut in the fabric at various points and the pressure necessary to start the tear is recorded together with the deflection at the time of tear.

Determinations of Properties of Doped Fabrics

Preparation of Samples. In the tests made by the Bureau of Standards the fabrics were stretched and tacked on frames under a tension of 80 gr. per cm. of width and doped in a room maintained at approximately 65 deg. relative humidity at 21 deg. cent.

The frames were 30 cm. by 30 cm. inside dimensions for the preparation of specimens for the determination of tensibility

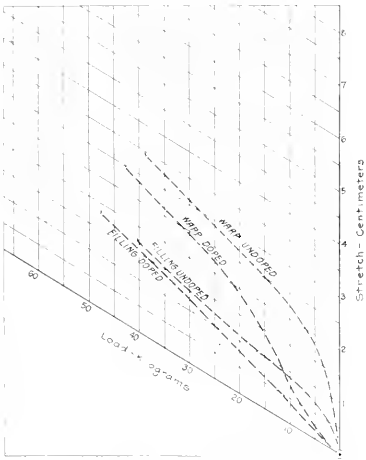

Fig. 5 Load-Stretch Relations of Standard A Grade Cotton Fabric

properties and 18 cm. by 61 cm. for determination of resistance to pressure.

The properties of doped fabrics were determined in the same manner as those of the undoped fabric, with the exception that the tensibility specimens were cut to 2.5 cm. width parallel to the line of threads.

Properties of Dope Films. Films of dope were made by painting the dope on glass plates and the films were subsequently peeled off and determinations made of tensibility and resistance to pressure.

Exposure Tests. The fabrics after tacking on frames and doping were placed on the roof and determinations made periodically of their physical properties.

Value of Tests

The determinations of weight, yarn size, crimp, thread count and twist are made primarily to explain difference in properties and more particularly to interpret properties in terms which readily adapt themselves to manufacturers' conditions. The effect of these values on properties will be indicated to give the reader a general conception of these effects.

The ability of a fabric to "take the dope" is influenced almost entirely by the relations between yarn number, twist, threads per inch, weight and weave, and they are practically the only measure of such a property. The functions of the dope are to produce a reasonably tight covering, to protect the

fibers from the influence of the atmospheric conditions and to produce a wind-tight surface. In order to perform these functions most advantageously it is necessary that one or two coats of dope penetrate the fabric enough to thoroughly protect the fibers and to serve as a necessary bond for the subsequent coats which should be more of the nature of a surface coating.

Crimp. The crimp of the yarn is the largest determining factor of the load-stretch relations of a fabric, particularly at the lower loads or under conditions of normal flight. This will be discussed under tensibility properties.

Tensibility Properties. The value of tensile strength as a measure of the quality of an ordinary textile material has long

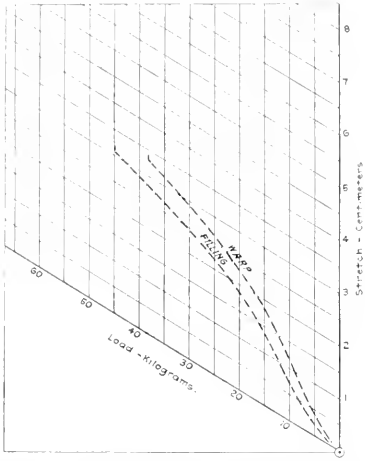

FIG. 6 LOAD-STRETCH DIAGRAM OF A 3/80'S UNMERCERIZED FABRIC DOPE

been realized, and it was largely the fact that this value was solely considered which misled investigators of cotton airplane fabrics.

An airplane-wing covering, for purposes of this discussion, may be considered as a flat, rectangular sheet supported on four sides, and subjected to pressure which may be considered as uniformly distributed over an area defined by the width of the rib spacing in one direction and relatively small distance in the other direction. The stress in the material of the section being considered is a function of the reciprocal of the radius of curvature plus a factor involving what is usually termed as an axial tension load. The curvature at any given pressure is determined by the load-stretch relations of the material, and although the load-stretch diagram does not consider the effect of axial loading, it does serve as a very valuable index to relative factors of safety of the various materials.

The wing covering must be airtight in order that the pressure may not build up on one fabric alone and that flight efficiencies may not be lowered. The material will remain wind-tight so long as the dope film is not ruptured or deteriorated.

The life of a fabric may be considered to be dependent upon the life of the dope. The dope may be caused to become deteriorated either by repeatedly exceeding its elastic limit or by exposing it to deteriorating rays of light. The latter condition may be reduced to a minimum by coating the material with pigmented varnish or dope which is opaque to the deteriorating portion of the spectrum. (This development may be attributed to an English investigator.)

The shape of the tensibility curves of the doped fabric serves as a valuable index as to whether the elastic limit of the dope will become exceeded under conditions of flight.

The ability of a fabric to shrink depends largely upon its load-stretch relations. The term shrinkage has been applied to refer to fabric tautness and leads to confusion as to the nature of the tightening. It has been observed that the fabrics having the least stretch at the low loads are tightest after doping, and that a plain-weave fabric is tighter than a fabric woven with fewer intersections and having less stretch. The fabric tautness is dependent largely upon the support which the fabric lends to the dope and the completeness with which the dope binds the yarns together in their crimped condition, and is dependent only slightly on film shrinkage.

The necessity of fabric tautness is believed to be largely dependent upon the psychology of the flyer, but, with the present dopes, fabric tightness is almost synonymous with life of the dope or fabric.

The relative recoverable stretch of an airplane-wing covering is quite readily indicated from an examination of the hysteresis loops of the load-stretch diagrams. It was not intended to convey the idea that all degrees of wing-covering looseness were equally desirable, and in the absence of exact data on the effect of fabric looseness on lift and drift, the allowable lack of recoverable stretch must be left to the judgment of the investigator.

The effect of the amplitude of the vibrations of a wing covering is, after a few flights, determined by the recoverable stretch of the material, and here again this phase of the in-

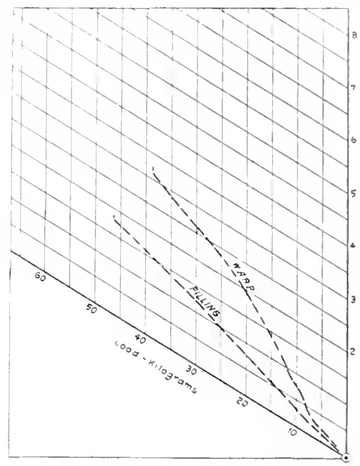

FIG. 7 LOAD-STRETCH DIAGRAM OF A 3/80'S MERCERIZED YARN

vestigation is not complete and the magnitude of this property must be left to the judgment of the investigator.

Tear Resistance, Tensibility Method. This method of determining tear resistance has been considered less applicable to wing-covering materials, as the value of the load-stretch relations is not fully realized, and has been superseded by the bursting-tear method.

The method may be used, however, in cases where the samples are too small for bursting tear and where such apparatus is not readily obtainable.

Resistance to Uniformly Distributed Pressure. As has been already pointed out, the stresses in an airplane-covering ma-

terial are a function of the curvature of the material at any pressure. It has been observed that the tensibility curve obtained by plotting calculated surface tension against stretch of the material during the application of pressure does not agree with the load-stretch diagram. The difference is probably due to the initial stress in the doped fabric and to the fact that the end and side effects of the tension strips are not present in the pressure test.

The test does not include the effect of tensions such as would result from wing deflections, but does serve as a more valuable index to factors of safety than the conventional tensile test. From the pressure-deflection curves it is easier to visualize the relative effect of wing deflection. The true conditions of flight are not duplicated, but the effect of the two systems of yarns are integrated and the results are less deceptive than those obtained from tensile tests.

Bursting-Tear Test. This test like the bursting test is a much better index to relative factors of safety than tension-tear tests. Questions of fabric reinforcement and balance of fabric are readily solved by a careful interpretation of the results obtained from such a test.

Results of Tests

Tensibility Properties. The load-stretch relations of a standard English Grade A airplane linen is shown in Fig. 4. It will be noted that the doped filling curve is practically a straight line. The doped warp curve shows a distinct yield point as indicated by the reversal of curvature.

Fig. 5 represents the load-stretch relations of a standard A grade cotton fabric, which, it will be observed, is very similar to the curve of the linen fabric.

The load-stretch diagram of a fabric may be divided into three parts according to the preponderating influences in these particular portions: (*a*) crimp; (*b*) crimp and yarn; (*c*) crimped-yarn characteristics. Referring to the warp load-stretch diagram of the cotton fabric, Fig. 5, the part of the curve extending to approximately 3 kg. is influenced almost entirely by crimp; the curve from 3 kg. to 10 kg. by yarn and crimp; the curve from this point on shows the characteristics of the yarn in its crimped condition.

This analysis suggests the particular part of the manufacturing process which should be varied to produce the desired shape of curve. The part of the curve below 10 kg. may be varied by changing the weave structure, stiffness of the yarn, and more particularly tension, on the yarns during weaving. The sum of the respective stretches of the warp and filling at this point is determined by the weave structure and the relative magnitudes of the respective stretches of the warp and filling are determined by loom tensions.

Fig. 6 represents the load-stretch diagram of a 3/80's unmercerized fabric doped. Both the warp and filling show a dope yield point between 5 and 10 kg. as is represented by the reversal of the curvature of the diagram.

The same construction of fabric made of mercerized yarn is represented by the load-stretch diagram, Fig. 7. The filling diagram does not show a reversal of curvature and the elastic limit of the dope will not be exceeded under normal conditions of flight.

Service tests on these two latter fabrics showed that the unmercerized fabric became somewhat mushy after a short period while the mercerized-yarn fabric stood up very well.

Similar tests on fabrics of various load-stretch diagrams showed that the fabrics whose dope-filling load-stretch diagrams were practically straight lines stood up exceptionally well.

The maintenance of the strength and the tautness of the cotton fabrics is dependent upon the completeness with which the dope protects the fabric and the completeness with which the dope is protected from deteriorating influences such as light and weather.

The dope penetration of the 3/80's fabric, 70 square, plain weave, is excessive. The dope penetration of the 2/60's standard fabric is slightly more than the standard linen fabric.

Excessive penetration of the dope reduces the tear resistance materially. If the standard 2/60's fabric is woven in a 2 by 2 basket the dope penetration is such as to cause an extremely low tear resistance. The small crimp in such a fabric makes it dope up very tightly.

Bursting Test. The curves, Fig. 8, represent the pressure-deflection properties of the center point of the fabric when subjected to air pressure, as previously described.

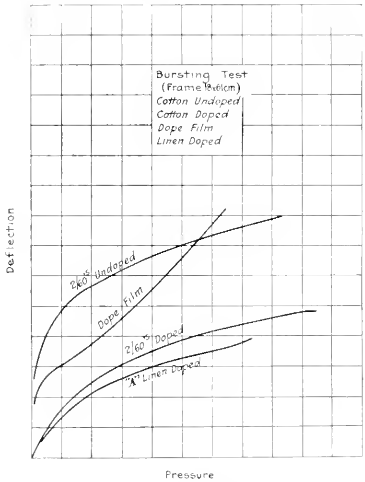

Fig. 8 Deflection of Center Point of Fabric When Subjected to Air Pressure

The deflection at any load of the fabric undoped is larger than that of the dope film. The deflection of the doped fabric is less than the deflection of either the fabric or the film. This further substantiates the theory that tautness is produced by the dope constraining the yarns in their crimped condition, and that in the standard fabrics the elastic limit of the dope is not exceeded.

It will be observed that the cotton fabric is capable of resisting more pressure than the linen, and it will have, therefore, a higher factor of safety. The fabric tautness is practically the same as that of the linen.

Tear Resistance. From an examination of the distortion of the lines about a tear, it is concluded that the tear resistance is a function of the strength of the individual yarns and the number being stressed. The number of yarns being stressed is dependent upon the load-stretch relations of the fabric and the weave structure.

[Other examples of tests are given in the complete paper.—Editor.]

Further experiments are being conducted to determine the properties of airplane fabrics, which have to do with the calculation of the exact performance of any fabric under any assumed condition of flight and which will include the effects of various rib spacings, wing deflections, vibrations, and the effects of various fabric structures.

MECHANICAL FEATURES OF THE VERTICAL-LIFT BRIDGE

By HORATIO P. VAN CLEVE,[1] NEW YORK, N. Y.

THE first important vertical-lift bridge was built in 1892 over the south branch of the Chicago River, at Halsted Street. Its span is 130 ft., it provides for city highway and electric railway traffic, and lifts 140 ft., affording vertical clearance for boats of 155 ft. This bridge is illustrated in Fig. 1.

The dead load is counterbalanced by a set of weights connected to the lift span by wire ropes which pass over grooved sheaves on the tops of the towers. The operating machinery is located under the roadway, at the base of one of the towers,

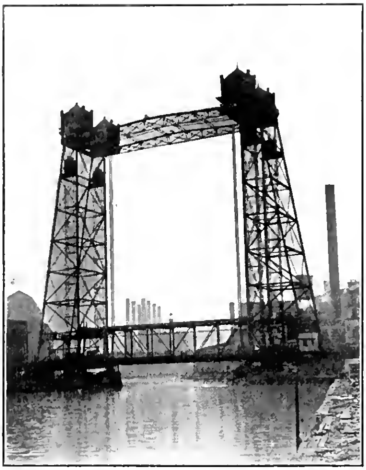

Fig. 1 Halsted Street Bridge Over South Branch of Chicago River, Chicago, Ill.
130 ft. span, 140 ft. lift. Design of J. A. L. Waddell, Kansas City, Mo

and the power is transmitted by a system of wire-rope drives running from the grooved drums in the machinery house to each end of the lift span, and to each counterweight. There are 16 ropes in all. Eight up-haul ropes, passing around a set of idlers at the bottom of the near tower, are carried to its top, where they divide into two groups. Four turn downward over another set of sheaves and attach to the near end of the lift span, and four, running horizontally to the top of the far tower, are there deflected downward and attach to the far end of the lift span. The eight down-haul ropes are connected in similar manner to the tops of the counterweights.

The towers, 217 ft. high, are steadied by well-braced lattice girders, which serve also as a support for the idler sheaves placed midway between towers to guide and steady the horizontal reaches of the operating ropes.

In the second structure of this type, of 229 ft. span and 40 ft. lift, built in 1909 across the Mississippi on the line of the Iowa Central Railroad near Keithsburg, Ill., several improvements were made on the operating mechanism of the Halsted St. bridge. Chief among these was the change in the location of the machinery from the pit below the tower to the top of the lift span. This shortened materially the length of operating ropes and reduced to a minimum the complications in their connection and arrangement; and it put the operator at once in reach of his machinery and in view of the river and approaching trains.

The scheme of operation, that used on nearly all succeeding lift spans, is as follows: The motor, in this case a gas engine, is connected by a train of gears to four spirally grooved operating drums, two over each top chord. Two operating ropes are fastened by rope clips to each of these drums, one for the upward movement of the span and the other for the downward, and are so wound on the grooves of the drum that the up-haul rope is wound on while the down-haul rope is paid off, and vice versa. An up-haul rope runs from each drum to the corresponding corner of the lift span, there over a double-grooved deflector sheave, and thence to the top of the tower, to which it is connected. The down-haul rope parallels the up-haul as far as the deflector sheave, and there, passing downward over the other groove in the latter, connects to the tower at a point in convenient reach of the deck.

Rotation of the drums in one direction winds on the up-haul ropes, causing an upward force at the deflector sheaves and thus, overcoming the friction of the tower sheave journals in their bearings, the unbalanced weight of suspending ropes and the inertia of the moving parts, lifts the span. All four of the operating drums are locked together by the connecting gearing,

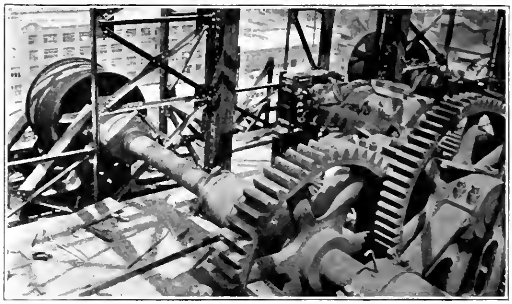

Fig. 2 Portion of the Operating Machinery, Bridge No. 458, Pennsylvania Lines
300-hp. railway-type motor, steel driving gears with 20-deg. involute-cut teeth, and operating drums.

thus insuring the synchronous rotation of the sheaves and keeping the span at all times parallel to its original position. Fig. 2 illustrates the general scheme of operation.

To keep the span in proper alignment between the towers, vertical tracks are provided on the four tower legs adjacent to it, and on these tracks bear the rollers which hold the span both in transverse and longitudinal alignment. Wedge-shaped steel castings at the foot of each tower engage close-fitting mating castings on the span when the latter is two feet above its seat. Automatic locks hold the bridge down when once seated. Each lock consists of two cams locked together by two segmental gears, and counterweighted to swing toward each other and grip a link hanging from the floor beam of the lift span. The cams are supported by a steel-casting anchor

[1] Chief Draftsman, The J. Edward Ogden Co., 147 Cedar St.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

bolted to the piers, and the link, in descending, separates them and is in turn held by them when the end of the span is 1 in. above its final down position. Unlocking is accomplished by a foot-shaped bar, sliding vertically on the floor beam and connected by a wire rope to the lock lever in the operating house.

The counterweights of the Halsted St. bridge were made of cast iron, but considerable money has been saved on the Keithsburg bridge and on all later bridges by making them of concrete. Each weight is placed between two vertical steel members connected at the bottom by one or more laced struts and ending at the top in the equalizing devices to which the suspending ropes are attached.

A patented form of equalizer which makes the sixteen ropes receive their load from a single pin effects a very material saving in space over the types using straight horizontal bars and vertical links, and has the advantage of being less seriously affected in the event of failure of one of the ropes.

The third important bridge to be built was across the Willamette river at Hawthorne Ave., Portland, Ore. The lift span is 244 ft. long and lifts 116 ft. In this design, the machinery, located on the center of the span, is much more compact than in the Keithsburg bridge, all gears being mounted in the same frame instead of being supported on isolated bearings bolted to different parts of the steelwork. Operation is by two electric motors.

Electric power is far superior to any other for lift-bridge operation, as it makes possible niceties in control; direct-current motors are the most economical to use because of their high starting torque in proportion to their size.

While the Hawthorne Ave. bridge was under construction another lift bridge of entirely different character was being

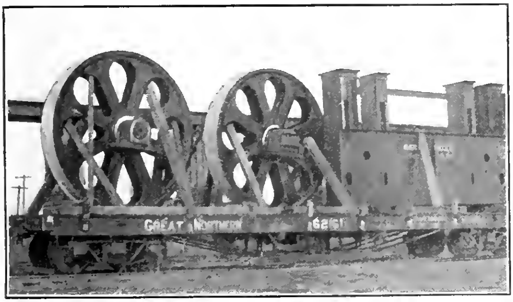

Fig. 3 Two 12-ft. Cast-Steel Sheaves and Supporting Girder, Missouri River Bridge at Mondak, Mont.

These sheaves weigh 7½ tons each and were built without any failures in casting.

designed. This was the 425-ft. span of the combined highway and railway bridge across the Missouri River at Kansas City. It consists of two decks, a fixed upper deck for highway and electric railway, and a lower deck for railway traffic, the hanger posts of the latter telescoping into the truss posts of the former as the lifting deck rises.

The live load coming on each lifting-deck hanger is carried by a pin into two saddle diaphrams in the upper deck truss. The dead load is carried into a pair of suspending ropes, which terminate in a counterweight after passing through the upper deck posts, over a deflector on the top chord, along the chord to the operating sheaves, and downward over another deflector. There are 15 panel points for each truss, and each point, except the two in the center, has one counterweight; the center points have two each, making 32 in all. There are two operating sheaves at each end of the bridge, and each pair is controlled by a motor and gear train near it. All suspending ropes pass over the four operating sheaves. The two sets of machinery, one at each end, are made to act together by means of two rope drives, one acting when the span is lifting, the other when it is lowered.

Each intermediate panel point of the lower deck is locked by a cam, and each end of the span is latched by a lock operated by a wire rope pulled by a segmental sheave in one of the machinery houses. All the hanger locks, 26 in number, and the two end locks, are operated by the same motor and gear train.

The Willamette river bridge of the Oregon-Washington Railroad and Navigation Co. is a combination of a simple lift

Fig. 4 Lift Span, Erected Position, Bridge No. 458, Pennsylvania Lines

The falsework is carried entirely on the piers and spread out from each of the latter in a fan shape upward to the panel points of the trusses.

span and the lifting deck just described. This lift span is 211 ft. long, weighs 3,420,000 lb. and lifts 89 ft., while the lifting deck below it can lift independently for 46 ft., and will then lift with the span for 89 ft. The advantage of this arrangement is that the highway traffic on the upper deck is not interrupted for ordinary river traffic, as the upper deck must lift for high-masted vessels only. There are five or six full operations daily and ten times that number of lower-deck lifts.

The large tower sheaves of this bridge are of 14 ft. pitch diameter, carry sixteen 2¼-in. ropes, and are made of cast-steel rim segments bolted to a center of rolled-steel plates and cast-steel hub. The sheave bearings are provided with a system of wedges which permits the replacement of the phosphor-bronze bushings.

The reason for making these large sheaves of built-up plates and castings was because of the difficulty of getting single steel castings of adequate size. However, considerable progress was made in three years in the manufacture of large steel castings. The two sheaves in Fig. 3, of 12 ft. pitch diameter and weighing 7½ tons each, were built without any failures in casting. They were used in the Missouri River bridge at Mondak, Mont.

In the bridge designed for the Vladicaucase Railway for a crossing of the Don River near Rostoff, Russia, the drums are close together instead of being at the opposite ends of the main drive as is the case with the Pennsylvania bridge illustrated in Fig. 2. The advantage in this arrangement is one of economy. A large gear reduction is made at the drums and there is only one line of shafting across the bridge. With the reduction used, the shaft is considerably smaller

than one of the two required in former layouts. The gear of one is also much smaller.

One of the heaviest bridges so far designed is that over the south branch of the Chicago River, near 19th Street, known

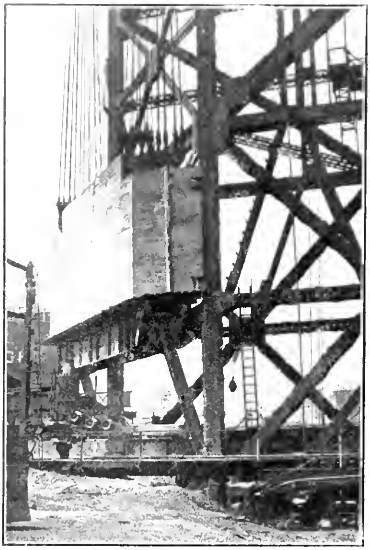

Fig. 5 Counterweight on Its Falsework, Bridge No. 458, Pennsylvania Lines

800 tons of concrete are supported on girders which deliver the load to two inclined struts bearing on 6-in. pins carried in saddle castings.

as bridge No. 458 of the Pennsylvania Lines. This bridge carries the double track of the Pennsylvania Lines and will be used by the Pennsylvania, the Chicago & Alton, and the Pere Marquette. There is no *closed season* on the river at this point and the Government required that the lift span should be erected 120 ft. above the river, the normal clearance for the span when lifted. As it was not possible to drive any piling into the river bed because of the resulting obstruction to river traffic, the falsework had to be carried entirely on the piers and spread out from each of the latter in a fan shape upward to the panel points of the trusses, as represented in Fig. 4. There were no connecting struts between the two sets of falsework and the upper end of the leaning members of each set had therefore to be tied back to the towers with steel bars and plates.

To erect the span with 120 ft. vertical clearance would have meant that these top chords of the falsework must in each case be attached to the tower legs half-way between two of the horizontal struts of the bracing, and as this was not considered advisable because of the resulting bending in the tower legs, it was necessary to erect the span high enough to allow these chords to come in line with the next higher struts. This placed it at 130 ft. clearance instead of the 120 ft. required. All connections were made in holes from which the rivets had for the time being been omitted.

On account of the shape of the falsework the erection of this span upon it would have developed an uplift in the shoes of the far tower legs too great to be safely carried by the anchor bolts, and it was therefore decided to build the concrete counterweights in such a way that their weight would be carried into these shoes. This was done (see Fig. 5) by supporting the 800 tons of concrete at each tower on girders which delivered the load to two inclined struts bearing on 6-in. pins carried in saddle castings riveted into the columns just above the bases.

There was nothing unusual in the erection of the towers, the derricks being stepped up from story to story according to practice common for similar structures. The heaviest pieces in them are the bottom sections of vertical legs next to the lift span which weigh 42 tons each. The four sheaves on the top of each tower weigh 31 tons each and are the largest of their kind so far built. They are of 15 ft. pitch diameter and each pair carries sixteen $2\frac{1}{4}$-in. plow-steel ropes, each weighing with its sockets about 2000 lb.

The span erection was carried on with two A-frame derricks shown in Fig. 4, the work progressing on the two sides simultaneously.

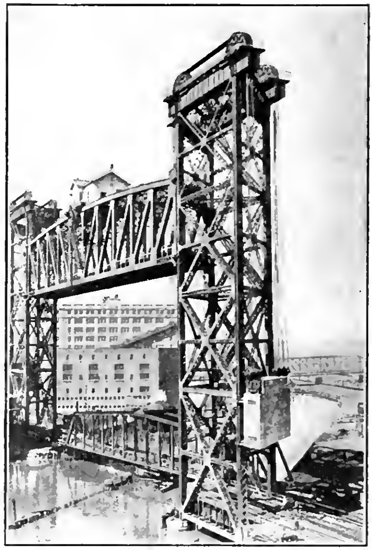

Fig. 6 Bridge No. 458, Pennsylvania Lines, After Removal of Falsework

The old swing span was kept in service until the upper structure was completed.

Only enough falsework to carry the end panel of the span was first set from the towers, and after the erection of these panels the derricks were moved from the towers to their first positions on the span, directly above the two sway frames nearest the ends. From here more falsework and more steel was erected and the derricks were again moved out. In Fig. 4 they are shown in their third and last positions as they stood to place the steel of the four center panels. To regulate the temporary camber to suit the erection of the last pieces of top chord, four hydraulic jacks were set beneath the bottom chord, immediately above the ends of the four last members of the falsework. Because of the eccentric loading on the towers there was bound to be some deflection of each tower toward the river, but calculations and measurements had been so carefully made that the two center pieces of bottom chord, 73 ft. 6 in. in length and weighing 36 tons each, when lowered into place fitted so exactly that the erection bolts could be entered without the use of drift pins. To get the last pieces of top chord in it was necessary to use the jacks.

Fig. 6 shows the bridge after the removal of the falsework and while the old swing span was still in service. This latter was partly under the new bridge, both open and closed, and as more than 300 trains use this crossing every day it was very important to take great care that nothing should be dropped from the span 100 ft. above. It is a matter for which the erecting contractor deserves congratulation that no accidents from this source occurred.

The new span is 272 ft. $9\frac{1}{2}$ in. long, lifts 112 ft., and weighs 1600 tons. At present it will be lifted at the rate of 15,000 times a year, for it lies near enough to the water to be in the way of every tug, but the great majority of these operations will require lifts of only a few feet. In a few years it is planned to raise the grade at this crossing, and the design of the bridge was carried out with this idea in view. Aside from raising the floor systems in the towers, lowering one story of tower bracings, and raising the base castings of the lift-span shoes, no change in this bridge will be necessary to accomplish this end. The span is operated by two 300-hp. series motors drawing their power from a 120-cell storage battery.

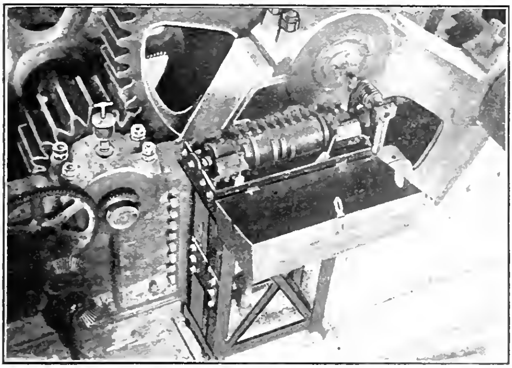

Fig. 7 Electrical Indicator and Limit Switch, Bridge No. 458, Pennsylvania Lines

Indicates by lights in the operator's house several points in the height traveled by the span, and cuts the controller circuit near each limit of travel.

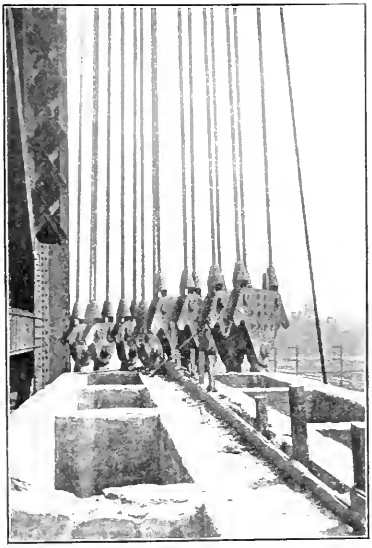

Fig. 8 Equalizer and Counterweight, Erected Position, Bridge No. 458, Pennsylvania Lines

When the span is lowered into place the parts of the equalizer become more closely packed together.

The electrical indicator and limit switch in Fig. 7, connected to the drive by worm-gear reduction, indicates by lights in the operator's house several points in the height traveled by the span, and cuts the controller circuit near each limit of travel, thereby breaking the main circuit, stopping the motors, and applying the solenoid brakes. Details of the equalizer and counterweight are shown in Fig. 8. Waddell & Harrington were the designers, represented in the field by the writer, and the Pennsylvania Steel Company were the contractors for fabrication and erection of superstructure.

DISCUSSION OF CERTAIN PROBLEMS IN REGARD TO MARINE DIESEL OIL ENGINES

By JOHN W. ANDERSON,[1] GROTON, CONN.

THE method of reversing used on the two-cycle engines is based on the fact that, in these engines, the spray and scavenger valves can be set right for running in the reverse direction by shifting the cams through a common angle. One camshaft running along the tops of the working cylinders operates all the valves; there is one cam for each spray and scavenger valve and the camshaft is shifted for reversing through an angle of 30 deg. The camshaft is shifted automatically by a slip coupling having a 30-deg. angle between the jaws, so that when the engine starts in the reverse direction, the crankshaft revolves 30 deg. before the camshaft starts, that is, when the timing becomes right for the new direction of rotation. The air starting valves are operated by two separate cams, one for ahead and one for astern, and the direction of rotation of the engine is determined by bringing into action the proper cam which in turn times the starting valve.

This automatic reversing mechanism fails to work satisfactorily when the engine is operated at low speeds, because then the engine does not turn exactly uniformly, and since the slip clutch is of the friction type, with jaws to limit the extreme travel to an angle of 30 deg., and since the camshaft and its parts have inertia of their own, this slip clutch fails to hold the camshaft in exact relation to the crankshaft. This upsets the timing of the valves, which in the case of the spray valve is important.

In the 1000-hp. engine installed in the single-screw submarine tender *Fulton* the shifting of the camshaft was made definite and positive by substituting, in place of the slip clutch, a sliding sleeve operated by a pneumatic cylinder under the control of the handling gear. The vertical shaft, which drives

[1] Engineer, Electric Boat Company.

For presentation at the Annual Meeting of The American Society of Mechanical Engineers, New York, December 3 to 6, 1918. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis by members upon application. All papers are subject to revision.

the camshaft from the crankshaft, is cut and the sliding sleeve connects the two parts; it slides on one of them on straight keys parallel to the longitudinal axis of the shaft, and on the other on spiral grooves, so that when the sleeve is moved along the axis of the vertical shaft the camshaft is twisted relatively to the crankshaft through the same angle of shifting used in the original design, namely, 30 deg.

To make the action still more positive, there is an automatic locking device on the pneumatic cylinder. It consists of a bar with two holes, connected to the lever operating the sleeve; corresponding to these holes there are two locking pins, one for each end of the pneumatic cylinder. The parts are so arranged that when the sleeve is in either extreme position, one of the locking pins fits into the proper hole in the locking bar and the parts are held securely in place.

When it is desired to reverse the engine, air is admitted by the handling gear to a piston on the locking pin holding the bar. This air pressure pulls the locking pin out, and when the pin is clear of the bar a port is uncovered leading to the pneumatic cylinder. The air pressure acting on the piston in the cylinder moves it to the other extreme position, setting the camshaft right for running in the opposite direction, and just as it reaches the extreme position it uncovers a port in the cylinder, admitting the air to the air starting valves on the working cylinders. Of course it is understood that when this gear reaches its new extreme position, the locking pin at that end of the cylinder registers with the hole in the bar and again locks the mechanism. The action is very simple and thoroughly foolproof and positive. This engine has been in service for some time now, and the reversing gear has amply lived up to expectations.

A similar method of reversing is used on the four-cycle engines, but unfortunately in this case it is necessary to have a separate camshaft for each kind of valve because of the different angles through which it is necessary to shift the cams in order to bring the timing right for the new direction of running. The engines are fitted with three camshafts, one for the spray valves, one for the inlet valves, and one for the exhaust valves. The air starting valves are operated by a single cam which is shifted by a separate mechanism to bring its timing right. The operation is pneumatic and the valves are controlled by plungers arranged radially around the single cam, in accordance with the proper sequence of cranks. All of the camshafts are shifted by means of a single pneumatic cylinder operating sliding sleeves similar to the one just described, except for the addition of a set of jaws on the camshaft which register with jaws in the sliding sleeve in its extreme positions and take the driving effort. The work of the spiral grooves is thus confined exclusively to shifting the camshaft. As in the two-cycle engines only a single cam is provided for each valve. This method of reversing has been applied to several engines and acts as satisfactorily in the case of the four-cycle engines as for the two-cycle.

The method of starting a Diesel engine which is almost universally used is by means of compressed air, and in most cases the air enters the working cylinders.

In starting, the air is ordinarily turned on for only a few seconds and in a few seconds more the engine can be brought right up to full power if desired. In fact, with a perfectly cold engine, the operation will be a great deal smoother under a moderate load immediately after starting than it will be at a very light load. This applies particularly at low speeds. For stationary engines which operate at full speed only, this condition is not encountered because the engine is brought up to full speed immediately after starting and the flywheel has inertia enough to keep the engine running smoothly even though ignitions are somewhat irregular.

In a marine engine the case is entirely different. Here it may be desired to start an engine slow ahead or astern, which, with a small, light, high-speed engine is difficult, unless a clutch between the engine and propeller permits the engine to be started up independently, warmed up, and then the clutch thrown in. The trouble in starting up when the engine is connected directly to the propeller is that in order to get the first ignition the fuel is turned well on, and when the first ignition does come there is enough energy in the combustion to overcome the inertia of the parts and drive the engine up to a much higher speed than is desired. With large, heavy engines this tendency is not nearly so marked and it is possible to get a slow, smooth start.

There are several ways to assist in getting a smooth start on a cold engine, and it is important to follow one of them in the case of large engines. One method is to heat the jacket water by turning steam in from an auxiliary boiler. In this way the cylinder walls can be warmed up to something approaching the working temperatures, and a smooth start is easily made. Another method, particularly useful in installations where very heavy fuels are used, is to start with a lighter fuel. By a lighter fuel is meant one that ignites readily and is more easily broken up so as to expose more surface to the heated air in the cylinder in the compression space, and thus give a quicker ignition. The solution to the problem of getting a good, smooth start consists essentially in having the temperature in the cylinders approximately the same as under working conditions and then injecting the fuel positively and regularly. Any method which does this will solve the problem.

Generally speaking, stationary engines and marine engines with clutches between the engine and propeller are fitted with starting valves on only half of the working cylinders. This means that while the engine is being turned over by starting air on part of the cylinders, the others are being warmed up by the compression, and even under very adverse conditions they soon reach such a temperature that ignition is obtained. In the case of reversing engines, the handling gear is sometimes modified to cause the starting air to be turned on and off the cylinders in groups.

The question of maneuvering is principally one of obtaining sufficient starting-air capacity, either by carrying a large number of flasks or—a much better way in the case of a large ship—by having an auxiliary compressor unit of good capacity. While the ship is maneuvering, the compressor unit is kept running all the time and pumps into the starting flasks. With such a provision an engine can be reversed repeatedly with only a very small starting-flask capacity.

In the case of small powers, it is much more convenient to use a clutch between the engine and propeller and employ a non-reversing engine which is kept running all the time.

The charge is often made against the Diesel engine that it is impossible to slow it down materially. This is true to a certain extent of the ordinary type of construction, but with the proper modifications any Diesel engine can be made to slow down and operate as readily at the lower speeds as at the higher. The solution of the problem consists in having a regular enough turning moment to keep the engine running fairly smoothly, and to obtain definite and regular ignitions in the cylinders. The case is much simpler for a large, heavy engine which has a big mass in the moving parts, and where there are a larger number of cylinders, say, at least six for a two-cycle engine and eight for a four-cycle engine, than it is for a small, light engine.

In the propulsion of a ship, the power drops off very rapidly as the revolutions are reduced, and therefore, at very low speeds, the power is so small that when divided up among all of the cylinders in the engine there is not enough fuel injected into each cylinder to give regular ignitions. This can be remedied in a large measure by cutting out half of the cylinders. The load per cylinder will then be more than doubled and the engine will run with very light loads at low revolutions.

Another method consists in the control of the spray-valve lift and timing by the operator. The control mechanism is so arranged that the timing and lift are changed at the same time. In some cases the valve is made to open at the same time under all settings and to close earlier, while in others it delays the time of opening by the same amount the time of closing is shortened. Both systems appear to work satisfactorily. When it is desired to slow the engine down, the fuel supply is reduced, the spray-valve lift reduced and the timing changed, and the spray-air pressure reduced somewhat. The combined effect of all these is to give regular ignitions in the cylinders, hence a smooth turning moment and good control over the engine. This method is much more preferable to cutting out some of the cylinders at reduced power, since it provides more impulses smaller in size and at closer intervals, which are all very vital points when running at very low speeds.

The advisability of fitting some sort of gear for controlling the timing and lift of the spray valve depends upon the type of engine and the place where it is going to be installed. Without such gear, an engine can be slowed down to about half speed without difficulty, hence for installations of small power in ships having a maximum speed of 10 knots or thereabouts it is unnecessary, because half speed means little more than steerageway. On the other hand, in the case of ships having a higher maximum speed such as 15 or 20 knots, it is very desirable to be able to slow the engine down to quarter speed or less, and then the installation of such a gear becomes almost a necessity. Under some circumstances, of course, it might be considered better to sacrifice maneuvering ability for the sake of simplification, but on engines of the size used on seagoing ships, the slight added complication due to this gear seems every bit worth while.

The question of lubrication is one that is dependent upon the type of engine. The gravity system is used successfully on large, open-frame, slow-speed engines, while on the small sizes, particularly where the crankcase is enclosed, a mechanical oiler is often used with leads to separate bearings or else a system of forced lubrication. There is one difficulty with the gravity lubrication and the mechanical oiler, and that is that there are many parts and pipes to consider, and each pipe or lead requires a certain amount of individual attention in order to see that the proper amount of oil is being supplied to that particular part. Furthermore, with these systems only just enough oil with a slight margin is provided to cover the necessary requirements of the bearing.

The big advantage of the forced-lubrication system is that a good surplus is supplied to each bearing at all times and distribution of the oil is secured by the proportions of the various passages, and hence requires no attention on the part of the operator other than to make sure that the main supply to the engine is kept up. Of course the various passages must be kept clear and open, but this is a matter that can be readily attended to during the overhauling period, and there is very little tendency for the oil to plug up the passages during operation.

There is one thing in connection with forced lubrication that is extremely important and requires constant watchfulness on the part of the operator, and that is the question of salt-water leaks into the lubricating oil. Any leak into the crankcase, no matter how small, forms an undesirable mixture with the lubricating oil, and at moderate temperatures creates a deposit which will quickly plug up the passages. If special precautions are taken against the leakage of the salt water into the oil, and the condition of the oil is watched carefully at all times, there is little chance for difficulty in this direction. From every other standpoint forced lubrication has the advantage over other methods. The proof of this is best shown by the increasing adoption of this system on engines of all types and sizes.

With an open-frame engine and using special precautions so that lubricating oil from the working cylinders does not drip into the crankcase, the oil does not become foul except after long service, but with the closed-crankcase trunk-piston engine the lubricating oil soon becomes fouled with finely divided carbon particles. After a time the oil turns very black and viscous and tends to clog the oil passages. This requires as much as 3000 hours' running in some cases, while in others this condition obtains in a few hundred hours. It is understood, of course, that oil is added from time to time to make up for the losses, but the system is not cleaned out and the whole supply replenished in all this time. As this condition of the oil is approached the danger of bearing troubles increases, and if it can be avoided the oil ought never to be allowed to get into such a condition.

Most of the carbon particles are removed by filtering, and the filtered product approaches the original in all its properties except that it is darker, due to the presence of the particles, which were not removed by filtering. The centrifugal process of clarifying is even better than filtering and removes a larger proportion of the carbon particles.

To attempt to filter or clarify the oil each time it is circulated through the engine would imply the addition of too much apparatus to take care of such a quantity of oil, and, fortunately, it is unnecessary. The best way is to drain out the system at regular intervals, depending upon the type of engine and the conditions of the service, and fill up with fresh oil. The fouled oil can be filtered at leisure and kept for future use.

The Diesel-engine industry is still so young that the question of how large an engine can be built is one that cannot readily be answered at this time. Practically all of the engines in service today are of small and moderate power as compared with certain steam plants, but, on the other hand, big strides have been made in the last few years in the development of large units.

In view of what has already been done and the experimental work that has been undertaken by so many firms, it is undoubtedly only a question of time when Diesel-engine power will be available for all except the very fastest liners and warships.

The vibration produced by an engine depends largely upon the number of cylinders and upon their arrangement. In commercial work, generally speaking, the speed is slow enough and the hull heavy enough so that the matter is not one of great importance; but in the case of a high-speed engine in a light hull, it is absolutely necessary that the engine be properly balanced.

For commercial work, many four-cylinder, four-cycle engines have been built, and these engines are very badly out of balance due to arranging the cranks all in one plane to get the best turning moment. But, as already stated, where these engines have been installed no serious difficulty has resulted,

due undoubtedly to the relatively low revolutions and the small size of the engine as compared with the hull.

If good balance is desired, it is necessary to use six or eight cylinders, which can be made to give the best turning moment and a good balance at the same time. The only thing that interferes with giving these engines a perfect balance is the air-compressor cylinders, but the reciprocating parts of these compressor cylinders are comparatively light, and hence do not cause any serious difficulty. In the case of crosshead engines it is oftentimes convenient to drive the compressors by beams and links from the crossheads. On a six-cylinder, four-cycle engine, for instance, there might be three compressors driven from three of the cranks, or on a six-cylinder, two-cycle engine three compressors would be driven from three of the crossheads and three scavenger pumps from the other three, so that a practically perfect balance would be obtained.

The usual method for the fuel system is to carry the main supply of fuel in the double bottom or in tanks in parts of the ship that are not ordinarily otherwise used, and then provide pumps for pumping it into gravity tanks placed well up in the engine room, so that the fuel can flow by gravity from the tanks to the engines. The tanks are made large enough to hold at least several hours' supply, and oftentimes a whole day's supply, so that the fuel has plenty of time to settle, and any sediment or water will collect at the bottom of the tank, where it may be drained off. It is very necessary that the fuel supply to the engine be perfectly clean. Very small particles of dirt or foreign matter will stick in the valves on the fuel pumps on the engine and cause no end of trouble. There is only one way to avoid getting this dirt into the engine, and that is to filter the fuel properly. The filter is sometimes placed between the gravity tank and the engine, and is sometimes combined with the gravity tank. In case the gravity tank is of small capacity, it is generally placed on the discharge side of the pump which pumps the fuel from the main tanks to the gravity tank.

The arrangement of the exhaust piping depends upon the type of the boat and the conditions of the installation. In the case of small boats, where the water line is more or less fixed and very little rough water is encountered, an underwater exhaust works out very satisfactorily, but in the case of large ships, the exhaust must be carried up a stack. In twin-screw boats it is essential that the exhaust from each engine be kept separate so that it can be watched by the operators. One of the simplest methods of detecting faulty operation in a Diesel engine is to watch the exhaust. The least sign of smoke is a sign of poor combustion and should be investigated at once.

Many varieties of muffler are used. The main idea of all of them is to break up the pulsations in the flow of the gases and give a steady flow. Where there is plenty of space and weight available, a big expansion chamber serves fairly well, but it is much better to reduce the size and use baffle plates. One of the best types is one in which the gases enter a cylindrical chamber tangentially at the circumference and escape at the center, or vice versa. Cooling the gases by turning the cooling water from the engine into the exhaust pipe helps too, but is not used except in some special cases. If there is very much sulphur in the fuel, water combines with the products of combustion and forms sulphuric acid, which will in time destroy the exhaust piping. If, however, the entire quantity of the cooling water passing through the engine is turned into the exhaust, the mixture is so dilute that there is little danger of trouble.

The piping itself must be jacketed or lagged, and due allowance must be made for expansion. Water jacketing is, in most cases, more satisfactory, but it adds to the complication and cost of the system, and for that reason is oftentimes avoided and the pipes are lagged.

The question of cooling the various parts of a Diesel engine is an important one, but as far as the fixed parts are concerned the problem is simple for all ordinary sizes of engines It is only necessary to provide for the proper flow of the cooling water, avoiding all pockets and dead areas. In the case of nearly all two-cycle engines and in four-cycle engines of quite moderate size, it is necessary in addition to cool the working piston, and herein lies a real problem. There is no exact dead line below which cooling is unnecessary and above which cooling is necessary, as a great deal depends upon the conditions of operation; that is, a high-speed engine designed to be driven at a heavy overload might require cooling, while the same engine driven at a lower speed and moderate power would operate perfectly satisfactorily with uncooled pistons. It is simply a question of carrying away the heat absorbed by the top of the piston. If it can be carried off fast enough through the cylinder walls to keep the center of the piston head from getting too hot, then the pistons do not need to be cooled, but if this is not so, then the extra heat must be absorbed by the circulation of a cooling medium through the piston. In general, it may be said that two-cycle engines developing 50 b.hp. or more per cylinder, and four-cycle engines developing 150 b.hp. or more per cylinder, are better off with cooled pistons.

The difficulties in the way of successfully cooling the piston are best shown by the variety of substances used and by the various devices employed to carry the substance to and from the piston. The simplest method is to employ a jet of air, but this is not very effective and can be used only where the cooling effect required is very slight. The other three substances employed to any extent are lubricating oil, fresh water and salt water. Lubricating oil has the distinct disadvantage that its specific heat is only about 0.4 of that of water, and hence about 2½ times as much must be circulated to carry off the same amount of heat within the same temperature limits. In addition, oil does not absorb heat from, or give heat to, a metallic surface as readily as does water. The one advantage of oil is that in case of any leakage inside of the crankcase, it mixes with the other lubricating oil and does not cause any damage.

In view of all this, it is readily understood why lubricating oil is used only in special cases where certain conditions make the advantages more than outweigh the disadvantages.

For commercial work it is safe to say that the choice lies between fresh and salt water. Fresh water requires an additional system, including tank, pump, cooler and piping, but it is not so corrosive, not so destructive to the packing in the joints of the system, not dangerous as regards deposits in the piston, and in case of leakage into the lubricating oil there is not the danger of damage to bearings. When salt water is used with proper precautions, most of the advantages of fresh water disappear; but it is a question as to how far these precautions can be successfully carried out under every-day working conditions. Both fresh and salt water will undoubtedly be used for some time to come until enough experience is gained with both systems to finally settle the matter either one way or the other, or it may be that fresh water will be used for high-grade installations, and salt water where first cost and simplicity are of prime importance.

To carry the liquid to and from the piston there are three general systems, but the details for any one system are varied greatly by the various engine builders or by the same builder

on different engines. One system is to combine the cooling with the lubrication system, but this, of course, is applicable only in case lubricating oil is used for cooling. The general scheme is to supply the oil to the main bearings, from whence it passes through the hollow crankshaft to the crankpin bearings and up the connecting rods to the wrist pins, thence through pipes or passages in the piston to the head and back again through a pipe or passage to some point near the bottom of the piston from where it can drain directly into the crankpit. A certain amount of oil leaks out at the bearings, and this serves to lubricate them.

A second system is to use jointed swinging pipes, and a third system, telescopic pipes. Both inlet and outlet pipes can be, and are generally, used so that any liquid desired can be employed for the cooling medium. The swinging pipes are suitable for slow-speed engines only, as at high speeds the inertia forces are very large and it is troublesome to take care of them properly. Moreover, the passage for the liquid must by the nature of the case have several bends and turns, and at high revolutions the inertia forces produce extremely high pressures, making it very difficult to keep the joints of the system tight.

There is one principle that must be followed in the design of swinging pipes for even moderate speeds, and that is to keep the bearings at the joints of the pipes entirely independent of the stuffing boxes, or, in other words, the piping for carrying the liquid, and the strength members for taking the inertia forces must each do its own work, although they are fastened together and are a part of each other. The great trouble with this system is to keep it tight at the joints, and it is only by careful designing along the lines stated that successful results can be obtained. In case water is used for a cooling medium, the lubrication of the bearings at the joints becomes important, but with forced lubrication there is generally enough oil flying around in the crankcase to take care of this if pockets, connected to the bearings, are provided for catching it.

Telescopic pipes are adaptable to both high- and low-speed engines. All parts are moving in line with the cylinder axis, and taking care of the inertia forces is much simpler than with the swinging links. Moreover, there are fewer turns in the passages for the cooling medium, and, as a general thing, air chambers can be placed so as to effectively care for the surges in the cooling liquids. An air chamber on the suction side is a necessity, but on the discharge side it may be dispensed with provided the discharge pipes are of generous size. It is good practice to put an open-end pipe discharging into a funnel, with proper provision against splashing, on the discharge line so that the cooling fluid coming from the piston can be actually seen by the operator. A certain amount of flexibility in the telescopic pipes is desirable, in order to remedy any slight looseness of the piston, or of the crosshead in its guide, or any slight misalignment. One method of accomplishing this is to provide a double pipe, one inside of the other. The inside pipe is fastened at one end to the piston or crosshead and at the other to the outside pipe. The outside pipe is guided in the part fixed to the engine frame. Here again the most troublesome part is the packing, but it is like packing the piston rod of an engine, and, as might be expected, the most satisfactory packing is of the labyrinth type, with provision for self-adjustment to the pipe so that it fits snugly under all conditions.

THE RELATIVE CORROSION OF CAST-IRON, WROUGHT-IRON AND STEEL PIPE IN HOUSE DRAINAGE SYSTEMS

By WM. PAUL GERHARD,[1] NEW YORK, N. Y.

A SPECIAL investigation was made in the summer of 1918 in New York City, with a view of bringing out facts regarding the deterioration by corrosion, and incidentally other characteristics, of cast-iron, wrought-iron and steel pipe as used in the drainage of buildings.

The plumbing of buildings comprises two distinct piping systems, namely, the *drainage* system (composed of sewer, drain, soil, waste and vent lines) and the *supply* system (composed of hot, cold and circulation pipes). The investigation was confined to the drainage and vent system.

The following kinds of pipes are used as materials for such drainage systems: standard or light and extra heavy cast-iron soil pipe (in 5-ft. lengths); light tarred cast-iron gas pipe (in 9-ft. lengths); standard-weight wrought-iron and steel pipe (in lengths of about 20 ft.), and finally extra heavy wrought-iron and steel pipe, both the steel and wrought iron being either black, asphalted or galvanized.

In the oldest plumbing installations standard cast-iron soil pipe was usually tar-coated or painted as a protection against corrosion. After about 1881 such pipe was not permitted to be used by municipal plumbing regulations, and extra heavy pipe took its place. Even this pipe was liable to have sand or blow holes, and its lead-calked joint was rarely permanent, as it was affected by extremes in temperatures.

These objections led to the introduction, in about 1881, of screw-jointed welded pipe with recessed drainage fittings, the late Mr. C. W. Durham, Mem.Am.Soc.C.E. having originated it. This system soon became the favorite one with the rapid growth of the skyscraper buildings in large cities. The earlier systems were of wrought iron, but since about 1890 steel pipe has also come into extended use.

In course of time severe corrosion occurred in some Durham drainage systems, and this led the manufacturers of cast-iron pipe to claim that both wrought-iron and steel pipe were not materials suitable for house drainage.

Great pains were taken in the investigation to distinguish between genuine wrought-iron and steel pipe, and the conclusion was reached that there was a vast difference in the corrosion of the two materials, and that steel pipe proved in actual service to be much inferior to the wrought-iron pipe.

The investigation involved the inspection of 78 buildings along both sides of Broadway, from Bowling Green (downtown) to 42nd Street. It included many modern office buildings and skyscrapers, also a few hotels and one large department store. The newer buildings, those less than 5 years old, were omitted from consideration, it being assumed that the corrosion of the pipes, if any, had not advanced suffi-

[1] Consulting Sanitary Expert, Hydraulic Engineer, Mem.Am.Soc.M.E.

For presentation at the Annual Meeting, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here presented in abstract form, and advance copies of the complete paper may be obtained gratis by members upon application. All papers are subject to revision.

[illegible] to [illegible] much information of value. The roof vent pipes of the buildings were selected because these formed almost the only parts of the drainage system, of which the interior could be freely examined. An attempt, however, was made to gain information regarding the main drain lines in the cellars.

The oldest buildings were found to have cast-iron drainage systems, but in the later buildings, and chiefly in those over ten stories in height, the screw-jointed system prevailed, doubtless because of its important advantages over the former.

Samples from over 500 wrought-iron and steel roof vents were taken for analysis to determine the material. The method

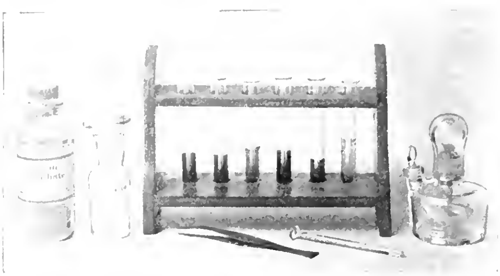

FIG. 1 MANGANESE TESTING OUTFIT

of testing was by the "manganese test." Small chips from the roof pipes were cut off by hammer and chisel, paint and galvanizing having first been removed with a file. The testing outfit used was a very simple one (see Fig. 1), and comprised a number of glass test tubes, with tube rack, a bottle of diluted nitric acid, a bottle of sodium bismuthate, an alcohol lamp, glass ladle and steel pincers. When the sample tested was steel, a decided pink color showed in the test tube, whereas if it was wrought iron, a brownish residue showed in the bottom of the tube. In numerous cases the chemical test was supplemented by a fracture test, showing the characteristic fibrous appear-

FIG. 2 CAST-IRON PIPE SHOWING TYPICAL CORROSION RESULTING IN EVEN POCKMARKING OR SHALLOW PITTING

ance of the break, if the material tested was wrought iron, and a bright crystalline appearance if the pipe was of steel. Doubtful cases were further investigated by referring larger samples from the roof pipes for microscopical examination to Prof. W. Campbell, of the Metallurgical Department, and for chemical analysis to Dr. Fales, of the Department of Chemistry, of Columbia University. Numerous photographs were also taken as a further record of conditions found.[1]

Two quite distinct forms of rusting or corrosion were observed, namely, pitting or pockmarking, and scaling or flaking. Both the wrought-iron and the cast-iron pipes were found to be evenly pitted to a comparatively shallow depth, thus reducing the pipe thickness but slightly (see Figs. 2 and 3). Many of the older steel pipes showed a characteristic and often aggravated form of scaling (see Fig. 4). When removed, the flakes often leave but a thin outer crust of the original metal; the scaling had a tendency to fall off by its own weight and to choke the vent pipes at angles or bends in the line.

While the genuine wrought-iron pipes made an excellent showing, the steel vents in service more than 20 years showed in nearly all cases a very bad deterioration.

As regards the drains and house sewers of welded pipe, a number of instances were recorded of pipes having become corroded, but only in a few cases could samples of the removed pipes be obtained for analysis. Assuming, however, the corrosive conditions to be no more severe in the drain pipes than in the roof vents, the drains would naturally last longer because of their larger sizes, which involve a greater wall thickness of the pipe. Concerning cast-iron drains, a few buildings still had the old light-weight pipes, and these were found without exception to be in bad shape, having leaky joints and sometimes holes, due either to corrosion or to the cutting of the pipes for the removal of stoppages, which were patched up with clamped bands. Where the house drains were of extra heavy cast iron, numerous instances of leaky joints were dis-

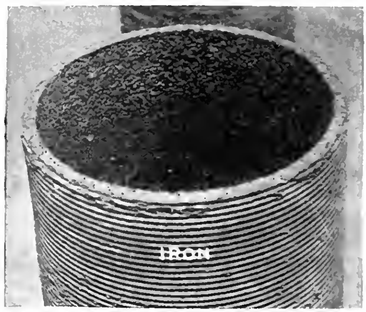

FIG. 3 WROUGHT-IRON PIPE SHOWING TYPICAL CORROSION RESULTING IN EVEN POCKMARKING OR SHALLOW PITTING

covered. This well-known defect of the calked joint in plumbers' pipe is particularly frequent where large volumes of hot waste water pass through the pipes, and also where steam exhaust, drip and boiler blow-off pipes are tapped into the house sewers. Municipal rules have for many years forbidden this practice, but it is still kept up, usually so after a building has been passed by the plumbing inspector.

The conclusions reached by the investigation may be summed up as follows:

1 Cast-iron pipe is a satisfactory material for house drainage purposes, many cast-iron roof vents showing up even more favorably as regards corrosion than had been anticipated, but the principal objectionable feature remains, i. e., the unsafety and unreliability of the calked joint, which can never be depended upon to be a permanently tight joint, because of expansion and contraction. A further objection to cast-iron drain and soil-pipe systems is that owing to the pipes being only five feet in length a much larger number of joints must be made, involving more labor in erecting and supporting the pipe stacks, and also the multiplied danger from leaky joints.

[1] Typical halftone illustrations appear in the complete paper.

2 The screw joint in welded pipe is much superior to the calked joint.
3 Steel pipe is much inferior to both cast-iron and wrought-iron pipe when exposed to corrosion. Galvanizing adds to the life of the pipe, but the coating does not adhere as well to steel pipes as to wrought-iron pipes. The rust resistance of the base metal is, however, of far greater importance than the preservative coating.
4 Ample evidence was obtained in this investigation to warrant the opinion that genuine wrought-iron pipe is a far more durable material for house drains and vents than steel pipe.
5 In recent years there has been a widespread substitution of the cheaper steel pipe where wrought-iron pipe was called for in the specifications. Then, again, engineers' and architects' specifications often make no discrimination between genuine wrought-iron and mild-steel pipe, and this is equally true of plumbing regulations.
6 Important municipal and governmental buildings, as well as those erected by private enterprise, all of which are expected to last from 50 to 100 years, should have all their important installations, and in particular those parts which are inaccessible after the building is completed, composed of materials having a corresponding duration of life.

In conclusion, one fact should be mentioned which may have contributed to the confusion as to wrought-iron and steel pipe, and that is that manufacturers and dealers have introduced the term *wrought pipe* for the purpose of designating steel pipe, when there appears to be no good reason why the material should not be called by its true name, viz., steel pipe.

This investigation as to the life of cast-iron, wrought-iron and steel pipe was in charge of the writer, and he personally inspected all buildings, witnessed all chemical tests, and

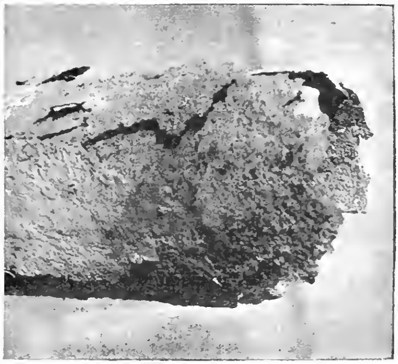

Fig. 4 Steel Pipe Showing Aggravated but Typical Corrosion Resulting in Flaking or Scaling

selected the typical vents which were photographed. The work was undertaken at the suggestion of the A. M. Byers Company, manufacturers of genuine wrought-iron pipe, of Pittsburgh, Pa.

WEIGHTS AND MEASURES OF LATIN AMERICA

By FREDERICK A. HALSEY,[1] NEW YORK, N. Y.

THE inquiry of which this paper is a report was conducted through a questionnaire of which about 500 copies were distributed throughout South and Central America and the West Indies. In order to secure representative and impartial distribution, outside agencies were enlisted in the work, the printed blanks being sent to their branches and correspondents by the National City Bank, the United Fruit Company, W. R. Grace and Company, and the Hill Publishing Company. Additional copies were sent out by the author to names taken from a commercial list obtained from the United Fruit Company and to United States consuls.

The questionnaire as drawn up in English will be found in the Appendix, together with the form letter which accompanied it. The actual printed forms sent out were translated into Spanish and Portuguese, in which languages most of the replies came back. The information given herein is not, however, limited to that obtained through the questionnaires as various citations in the text point out. In all cases, quotations without names attached are from the questionnaires.

Spanish and Portuguese Weights and Measures

As many readers are not acquainted with Spanish weights and measures, tables of the more common units and their relations are here given. The translation of the names is almost self-apparent, but the following are given:

Onza	Ounce	Pulgada	Inch
Libra	Pound	Pie	Foot
Tonelada	Ton	Vara	Yard
Cuartillo	Quart		

The Portuguese names are so similar that their meanings will be apparent.

SPANISH WEIGHTS AND MEASURES

Weight		
16 onzas	=	1 libra
25 libras	=	1 arroba
4 arrobas	=	1 quintal
20 quintales	=	1 tonelada
Dry Measure		
4 cuartillos	=	1 celemin
12 celemins	=	1 fanega
12 fanegas	=	1 cahiz
Liquid Measure		
4 cuartillos	=	1 azumbre
8 azumbres	=	1 cantara
16 cantaras	=	1 moyo
Length		
12 pulgadas	=	1 pie
3 pies	=	1 vara

Unification of English and Spanish Weights and Measures

With slight differences in the values of the units, this system is substantially identical with our own. With suitable foresight and effort the two might have been unified long ago.

[1] Commissioner, American Institute of Weights and Measures. Mem. Am.Soc.M.E.

Abstract of report prepared for the American Institute of Weights and Measures. For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. Advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

The chief difficulty in the adoption of the metric system in Latin America has been and is the psychological difficulty—that is, learning to think or vizualize values in strange units. In this sense the difficulty of adopting the English values of the units would have been nil for there would have been too little change in values to cause confusion of thought, while in names there would have been none.

Meanwhile the still greater difficulty in our own case—the physical difficulty due to the anchorage of units in standardized manufacture—was and is absent in Latin America where but little manufacturing is done. The difficulties in the way of adopting the English values of the units thus were and are trifling in comparison with those in the way of adopting the metric units. Moreover, the process would have been one of subtraction, two sets of values being reduced to one, and, internationally considered, several sets of values reduced to one, for the Spanish units have slight and annoying differences of value in different countries. The "adoption" of the metric system, on the other hand, has been one of addition, another set of units being added to those already existing.

The ease with which the English values of the units might have been adopted is shown by these reports of the progress they have made. With no trace of compulsion or even governmental recognition, they have come into large use by the operation of the forces of trade and commerce and by simple acceptance, whereas the metric units have nowhere made progress except by compulsion.

The remaining question is: Is it too late? Except for units for land measure, which, once established, should be let alone, I think not, for conditions have not materially changed in Latin America. It must be apparent there, as this inquiry makes it here, that the attempt to adopt the metric system is a failure. The weights and measures of Latin America are in a state of chaos, for which a remedy is sorely needed. Were they to dismiss the intruder and retain the old historic names with changes in values which are so slight as to be inappreciable for most purposes, Pan-Americanism in this important field would become an accomplished fact, and the unification of the weights and measures of North and South America with those of the British Empire would be within sight.

It is especially to be noted that until about the beginning of the present century there were few, if any, compulsory metric laws in Spanish America. The system had been "adopted" in many of those countries as the official system, and used chiefly for customs purposes and railway tariffs, but the people continued to use the old measures without molestation. The change in the intervening years is due to German influence and for German purposes. If, as seems probable, German influence in Spanish America is to suffer an eclipse, is it too much to hope that the future may see the unification of the weights and measures of North and South America and the British Empire on the foundation of the system which, in its basic and historic features, is common to all?

Meanwhile we have an important lesson to learn from Latin America. A glance through these reports will reveal the common practice of selling grain and other farm products at wholesale by *weight*, the arroba and the quintal being favorite units.

Our clumsy efforts to connect the bushel and pound through conversion factors are the cause of much confusion[1] which would disappear were we to copy this practice, and, incidentally, deprive the metricites of a false argument which is on all their lips. and which the unthinking know no better than to accept. The unit for this purpose should be the quintal of 100 lb.—a name which is preferable to hundredweight as it avoids confusion with the British hundredweight of 112 lb.

General Analysis of Results

The effort to learn the relative usage of the different systems has not been successful. When one return gives exclusive use of the metric system for a given purpose and another exclusive use of the Spanish system for the same purpose, discrimination is impossible. The thing here proven is that the claim that Latin America is metric is false, as are all arguments based upon it. In particular it should be noted that the order in which the units are herein named has no significance.

In but one of the countries investigated (Uruguay) can the metric system be said to be adopted for domestic trade, while there we find an authorized official exception in the case of real estate, as we find other exceptions in the cases of wearing apparel, industry, and navigation. Nevertheless, in twelve of these twenty countries, according to a report on The Metric System in Export Trade by the Director of the Bureau of Standards, the metric system is "obligatory."[1]

In ten of these countries (apart from the railroads and other fields under immediate government control) the metric system has made almost no impression. (Nicaragua, Guatemala, Spanish Honduras, Cuba, Panama, Colombia, Porto Rico,[2] San Salvador, Ecuador, and Costa Rica.

Of these ten countries, according to the above report, the metric system is "obligatory" in seven. In five of them (Cuba, Colombia, Porto Rico, Panama, and Spanish Honduras) the English units are used far more than the metric, having largely supplanted all others, although in three of them, according to this same report, the metric system is "obligatory." Not only has the English pound come into large use, but the arroba and quintal have been adjusted in value to make them equal to 25 and 100 English pounds, respectively. In substantially all of the countries investigated the English inch is used for mechanical purposes, as the English nautical units are used for navigation and sea shipments. That most derided of English units—the nautical mile—is used by all countries that sail the seas and they use no other. The kilometer is an unknown measure at sea.

In all countries the impression made is in direct relation to the severity of the laws, of which we have the climax in Uruguay, with Venezuela and Argentina not far behind. In all cases the movement was begun with mild laws under the impression that the adoption of the system was a simple and easy thing to bring about. Such laws failing, more drastic ones followed, but even these have been but partially effective. The greatest progress has been made in the field of domestic retail trade, in which weights and measures are under the immediate eye of officers of the law.

It is this field which comes under the observation of tourists. One may tour through, or, for that matter, live in a country for many years, in many walks of life, and experience but

[1] It should be noted that the adoption of the metric system would not do away with this confusion since wheat, corn, rye, etc., do not weigh the same per decaliter any more than they do per bushel. The sal of these and similar commodities by *weight* is the simple and sufficient method of abolishing all the confusion now experienced in this branch of trade.

[1] See The Metric System in Export Trade by the Director of the Bureau of Standards, page 17; Senate Document No. 241, Government Printing Office, 1916.

[2] Porto Rico is always claimed to be metric by the advocates of the metric system. But, according to Mr. Fred R. Drake, Chairman Executive Committee, American Metric Association, "The meter, liter and gram continue to prove most satisfactory in official and general use in the Philippine Islands, *Porto Rico* and other United States possessions."

little contact with weights and measures outside the field of retail trade, and we thus see why the reports of tourists are more favorable to the metric system than the facts justify, as we also see why the observations of tourists, in a comprehensive sense, have very limited value.

The further we get from the field of retail trade, the less is the system used. In this field the progress is chiefly with units of weight and capacity, the measure of length for the sale of drygoods being commonly the vara, while imported wearing apparel of all kinds is commonly sold by the units of the country of its origin, by the inch at least as much as the centimeter, and domestic products are frequently made to numbered sizes, of which the relation to any system of units is not apparent. They are not metric.

In primary or wholesale markets the old measures prevail, although these, in some cases, have been adjusted in value to make them even multiples of English basic units. We have here perfect examples of the simple process of unification of English and Spanish measures which, with proper encouragement, might by this time have become substantially universal.

Lumber and timber are almost universally sawn to the inch, although frequently mixed with the vara or the meter for length, and the square and cubic meter as sales units, prices being made at so much per square or cubic meter for one-inch boards.

In the mechanical trades tailors and seamstresses use all three systems, as do stone and brick masons, while carpenters commonly use the pulgada or inch. In machine shops both English and metric units are used, depending chiefly on the country of origin of the machines they have to repair. The inch is predominant.

In this connection we have the report of the Cleveland Twist Drill Company that shipments of their tools to South America are "95 per cent to 100 per cent English," and of the Detroit Twist Drill Company that "All of our South American customers use more English sizes than metric." Needless to say, English-sized twist drills are bought in order to make English-sized holes, for they will make no other.

In ship and boat building, also, the English units find large use, while in mining and smelting we find a miscellaneous mixture of all three systems.

The persistence of old units is most pronounced in the measurement of land. When units of measure are once anchored in titles to real estate, they are there to stay. Of this we have perfect examples in the use of the French arpent in Louisiana and the Spanish vara in Texas, in which states those units are today the common units of land measure. Another example is found in France, where, in some sections, the old units of land measure are still predominant.

When outlying districts are incorporated within city limits, parcels of land are much reduced in size and smaller units come in. This gives an opportunity for the introduction of the metric system, but with the result that, in the older portions of the town, the old units are used, while in the newer portions we find the new ones.

Similarly, initial surveys of the *hinterland* give an opportunity for the use of new units, but again with the result that the older portions of the country are measured in one set of units and the newer in another.

In Uruguay, where the laws are more severe and more rigidly enforced than in any other country, it has been found necessary to authorize the use of old units for the measurement of land (see Uruguay below), while in other countries the laws, in this application, are quietly ignored. This is the more significant because all transfers of real estate, as matters of public record, come before the eyes of officers of the law. In other countries, again, the purchase and sale are made in Spanish units and the day is then saved by inserting metric equivalents in the documents of record.

In marine measurements and sea shipments the English system is used everywhere, although mixed with metric units, especially for inland navigation.

Classified in another way, the most-used metric units are those of capacity. Next come those of weight, and, trailing far in the rear, those of length and their correlatives of area. This is in accordance with a law which long ago made itself apparent.

The Reason Why Compulsory Metric Laws Fail

A few words in explanation of the failure of even drastic laws for the adoption of the metric system are here appropriate. Such laws fail because established and harmless practice cannot, except in a technical sense, be made a crime. Fancy an American grocer arrested, haled to court, fined, and even sent to jail for selling sugar by the pound—a thing that has been done since the Pilgrim fathers landed at Plymouth Rock. And yet this is exactly what they do in Uruguay. Place a meter and a yardstick alongside. They differ in value by about 10 per cent. Is it conceivable that selling by one can be made a virtue and by the other a crime? Fancy an American jury convicting a merchant of a crime for selling drygoods by the yard! And yet this is precisely the meaning of compulsory laws.

It is a truism of law that excessive penalties cannot be enforced and so defeat themselves, and is it not clear that compulsory metric laws in any country in which the people have rights are unenforceable, and that the more drastic they are, the more unenforceable they become?

Theories Disproven

On its face, this Report sets forth a volume of facts regarding the weights and measures of Latin America, but, in addition to this, it disproves many theories.

The first theory is that it is an easy and simple matter for a country to change its system of weights and measures. Here we have the results of twenty attempts to bring about this change, most of which date from about the middle of the last century. In most of them the result has been grotesque failure, while in none has the attempt to retire old units been successful.

It is on this theory that the entire metric case is based. Once one has accepted the idea that a country may easily change its weights and measures, it is a short step to the conclusion that those who have tried it have succeeded, and then another short step to the conclusion that we can succeed. The question at issue is one not of belief but of fact. With 20 failures after, in most cases, more than half a century of effort, the fact is proven.

The second theory is that the adoption of the metric system does away with confusion of weights and measures. These reports show that the actual result is to increase and not eliminate confusion.

The third theory is that the metric system is in universal use, except in the United States, the British Empire and Russia. These reports show that in no country investigated is the system universal.

The fourth theory is that we must adopt the metric system if we are to succeed in selling goods to Spanish America. These reports show that if we are to change our weights and

me[illegible] order to conform to the practice of Spanish America, we should adopt the Spanish and not the metric system.

The fifth theory is that the "adoption" of the metric system leads to an important saving of time in primary education. Clearly, with a mixture of systems in use, children have more and not less to learn.

The sixth theory is that the adoption of the metric system leads to a saving of time in calculations. Clearly, with this mixture of systems in use, involving the constant necessity for conversions between them, the labor of calculations is increased and not reduced. For example, consider the purchase at wholesale by the meter and the sale at retail by the vara.

The seventh theory is that the persistence of old units in metric countries is a persistence of names but not of things — that the practice is nothing more than the use of old names for new units. One of the most recent formal statements of this theory is by Dr. William C. Wells, Chief Statistician of the Pan American Union, who says (*Bulletin* of the Pan-American Union, January 1917):

"It has been found somewhat difficult in countries adopting the metric scale to do away with the names of the most-used measures such as yards, quarts, pounds, miles, etc., or rather of the equivalents of those English words in the language of the country adopting the metric system. . . . It has been found very easy to substitute the thing, although sometimes difficult to substitute the word. . . . Scarcely a vestige of the old system is left in any country that adopted the metric system. Now and then in Latin-American countries one will hear the old words, but almost always with a meaning adapted to the new scale."

These replies are sprinkled with such expressions as these: "Same as in the United States." "English sizes." "For distance, the English mile." "English and metric system." "French and American indiscriminately." "Thickness of lumber is always in English inches." "Metric system infrequently." "The two standards are used indiscriminately." "The meter is used very little." "The artisans of the country use in their calculations the Spanish vara as their standard." "Our standard of weight is the quintal of 100 Spanish pounds." "The people continue to use the old Spanish measures." "At retail, vara; at wholesale, yard, meter." "While the metric system is legal it is not enforced." "In domestic business, only the Spanish system is used." "A few French articles are in metric sizes." "The cuadra is still commonly used, but is prohibited in the documents." "The English measures prevail." "Generally the English foot, exceptionally the meter." "The old Brazilian system is still commonly used." "Cloths are sold indiscriminately by meters, varas and yards." "Occasionally the metric ton." "The metric measurements are sometimes used."

Such expressions as the above, of which there are many more, cannot be thus explained.

Many of these reports *give values of the Spanish in terms of metric and English units* which show that the old names are not used for the new units, as for example:

From Costa Rica: Vara, 0.836 meter; libra, 460 grams; cuartillo, 1.165 liters; botella, 0.67 liter; manzana, 6988 square meters.

From Argentina: Vara, 0.866 meter; pie, 0.289 meter; libra, 0.4594 kilogram; tonelada, 918.8 kilograms.

From Nicaragua: Vara, 33 inches; libra, 16 onzas; fanega, 288 libras; manzana, 10,000 square varas.

Not one of all of these hundreds of sheets contains a single item to substantiate the theory advanced by Dr. Wells. No proof of it has ever been offered; it is clearly untenable and must be dismissed.

The eighth theory is that we will use metric equivalents for English sizes, or, as the metric party put it, "Whatever is manufactured must be actually the same size or weight as before. It is merely a matter of a new term of expression." Nothing to justify this theory can be found in these papers, no single example of this practice being found therein. Articles manufactured to the inch (wearing apparel, pipe, lumber, etc.) are uniformly sold by the units to which they were made.

The Result of a Great Series of Experiments

We have in this Report a composite picture of the result of many attempts to adopt the metric system, that result being uniformly the addition of that system to those previously prevailing, and it is this that we must contemplate as the result of the attempt to adopt it here. We must compare what we have with what we will get, not with what one may hope we will get. Moreover, it must be noted that had all these countries succeeded in this great experiment, it would have no significance for our guidance, because of the greater importance of our manufacturing industries. France adopted the system before the beginning of the manufacturing era, and Germany adopted it before the development of manufacturing in that country. Every one knows that the rise of Germany as a manufacturing nation began after the war of 1870. South American countries are not manufacturing countries. More manufacturing is done in the city of Philadelphia than in all South America.

We see, then, that in western Europe the system was adopted before the development of manufacturing and that manufacturing has developed with and in it, while in South America practically no manufacturing is carried on.

Great Britain and we are the first to be asked to change our manufacturing units, for which there is not a shadow of a precedent.

Seldom has an effort of such magnitude been made. We have here a record of twenty experiments on a national or, collectively, a continental, scale, and their net result is to demonstrate the wisdom of the conclusion arrived at by John Quincy Adams after four years of investigation and nearly a century ago:

"The substitution of an entire new system of weights and measures instead of one long established and in general use, is one of the most arduous exercises of legislative authority. There is, indeed, no difficulty in enacting and promulgating the law, but the difficulties of carrying it into execution are always great and have often proved insuperable.

"The legislator . . . finishes by increasing the diversities which it was his intention to abolish, and by loading his statute books only with the impotence of authority and the uniformity of confusion."

It is to protect our country from this "uniformity of confusion" that we are fighting.

The Results Are Not Surprising

Some who read this Report will, no doubt, be surprised at the condition disclosed in Spanish and Portuguese America, but there is no reason why any one should be surprised as no one has seen the first scintilla of proof to the contrary. Assertions and assumptions have been repeated so many times that, no doubt, in some cases, they have been accepted as true, but no proof has been presented and there is no proof. On the contrary, those who know weights and measures, who know the gigantic character of the task which confronts any nation

which sets out to change them, know that the inherent probabilities are all in favor of the condition set forth.

Do not confound legislation for the adoption of the metric system with its real adoption. All experience shows that while such legislation is fatally easy, the adoption of the system is impossible, the effect of the laws being to bring about nothing but the confusion and disorder that prevail throughout Latin America. Every success in the attempt to persuade some interest to introduce the system is but a step toward the confusion that prevails throughout Latin America. We have there twenty countries in which the experiment has been made with the uniform result of grotesque failure. Every expectation has been falsified and every prediction inverted. Shall we take warning, or shall we plunge headlong into this metric morass?

APPENDIX

Form of Letter Which Accompanied the Questionnaires

My Dear Sir:

The American Institute of Weights and Measures, which is composed of many of the leading engineers and manufacturers of this country, is engaged in an extended investigation of the subject of weights and measures, and it desires to obtain at first hand definite information regarding the units of weight and measure (Spanish, metric, and English) as applied to the trade, commerce and industry of South and Central America. With this in view, the accompanying list of questions has been drawn to which we ask you to kindly reply for your locality.

The thorough character of the investigation which this Institute is undertaking will, we hope, impress you with the importance of this questionnaire, since, when all the replies are assembled, they will constitute a mass of information which is not now in existence.

It is particularly desired that answers shall be forthcoming from the smaller towns of the interior as well as from the principal cities of Latin America AND FROM INDUSTRIES AS WELL AS COMMERCE in order that the usage of weights and measures among the people may be learned. To this end we ask you to kindly make inquiry among contractors, builders, manufacturers, and, if necessary, among artisans.

Please distinguish carefully, when necessary, between the metric and English tons, between the half-kilogram and the Spanish and English pounds, the Spanish and metric quintals, and the Spanish pulgada and the English inch. When two or more units are used for the same purpose, please name them in the order of their frequency. When one unit is chiefly used, please place after it the word "Chiefly" and similarly, when one of the units is used but seldom, kindly place after it the word "Infrequent."

Your reply, esteemed sir, will place us under lasting obligations which we trust we will at some future time have the pleasure and satisfaction of discharging. In the meantime, we beg to subscribe ourselves with every consideration of respect and esteem.

Most cordially yours,

American Institute of Weights and Measures,

.... *Commissioner.*

Questionnaire No. 1

What are the units of weight and measure commonly used with relation to the buying and selling at retail of the following products?

Groceries	Flour
Fruits	Tea and coffee
Milk, butter and cheese	Dry goods
Other farm products	Fuel
Hardware	Tobacco
Fish	Miscellaneous
Meat	

Questionnaire No. 2

What are the units of measure commonly used with relation to buying and selling articles of clothing, as follows?

Ready-made clothing	Shoes
Hats	Gloves
Collars	Corsets
Underwear and hosiery	Miscellaneous

Questionnaire No. 3

What are the units of measure commonly used with relation to the sale of lands and filing of papers and deeds, as follows?

In the farming districts
In the smaller towns
In the cities

Questionnaire No. 4

What are the units of weight and measure commonly used in the following industries?

Lumber and timber (length and thickness of boards and sizes of timbers)
By carpenters and other woodworkers
By tailors and seamstresses
By blacksmiths
In machine shops
In contracts for excavation of ground
In mines and for mineral products.
In smelting and for smelter products
Sizes of pipes for gas, water, sewers, etc.
In ship and boat building
Marine measurements (distances, maps, charts, tonnage, drafts, freight rates, etc.)
Miscellaneous

Questionnaire No. 5

What are the units of weight and measure commonly used with relation to the buying and selling of farm products at wholesale as follows?

Hay	Milk, butter and cheese
Grain	Garden products
Meat	Rubber
Root crops	Miscellaneous
Coffee	

Questionnaire No. 6

What are the units of weight and measure commonly used with relation to transportation tariffs?

Railway tariff for passengers and freight (load and distance)
Loads and rates for city transportation
Loads and rates for transportation by muleback across the mountains
Railway track gages and length of lines
Railway equipment (units used in the construction and repairing of locomotives, cars, etc.)

The Hill Publishing Company's questionnaire was considerably abbreviated from the above.

REPLIES TO THE QUESTIONNAIRES

In the complete report are summarized in great detail the replies to the questionnaires as received from the following countries: Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, Guatemala, Haiti, Mexico, Nicaragua, Panama, Peru, Porto Rico, San Salvador, Spanish Honduras, Uruguay, Venezuela. As typical of the replies, the summary of the replies from the largest country, Brazil, is here given:

BRAZIL

(Summary of thirty-seven returned questionnaires)

Groceries: Liter, kilogram, gallao, arroba, gram. *Fruits:* Kilogram, arroba, alqueire; conserves in ½-kilo cans. *Milk:* Liter, garrafa of ⅔ liter. *Butter and Cheese:* Kilogram, libra; butter in packages of ½, 1 and 7 pounds and ¼, ½, 1, and 3 kilograms. *Other Farm Products:* Cargueire, quarta, kilogram, metric pound, liter, arroba. *Hardware:* Inch, kilogram, meter, centimeter, millimeter, metric ton, liter (*sic*). "Use all measures." *Fish:* Kilogram. *Meat:* Kilogram, liter (*sic*); arroba. *Flour:* Liter, kilogram, alqueire. *Tea and Coffee:* Tea in cans of ¼, ½, 1 and 5 English pounds and by kilogram; coffee, kilogram.

Dry Goods: Meter, jarda, covado.

Fuel: Wood, cubic meter, carroca, cargneire; coal, metric ton, kilogram; oil, kilogram and liter.

Tobacco: Kilogram, meter, arroba; fine tobacco, onca.

Ready-Made Clothing: Centimeter, meter. *Hats:* Brazilian, English, Italian and Portuguese numbers, centimeter, inch, meter (*sic*). *Collars:* Centimeter, meter (*sic*). *Underwear and Hosiery:* Underwear, centimeter; hosiery, inch, centimeter, meter. *Shoes:* Centimeter, numbered sizes by no apparent system, English, Portuguese, meter (*sic*). *Gloves:* Letter sizes, numbered sizes by no apparent system, centimeter, inch. *Corsets:* Centimeter, meter (*sic*).

For the Measurement of Land: In the farm districts — meter, square meter, alqueire, hectare, legua, braca, are, palmo, pollegada (sic), paulista, front foot, tarefa. "For agricultural lands or open lands in general the division is almost universally into alqueires." "The old Brazilian legua is generally used." "The standard throughout the State is the alqueire." In the smaller towns — braca, alqueire, square meter, tarefa, vara, hectare, palmo, front meter, are, pollegada (*sic*). In cities — meter, square meter, braca, are, palmo, pollegada (*sic*), hectare.

Lumber and Timber: Palmo, foot, inch, pie, pollegada, meter and palmo for length, square foot, cubic meter, centimeter. "Thickness of lumber always in English inches. Width in English inch by the lumber company, and Portuguese inch by others. The lengths in feet by the lumber company and Portuguese inches by others."

By Carpenters and Other Woodworkers: Meter, inch, foot, palmo, pollegada, centimeter. *By Stone and Brick Masons:* Meter, cubic meter, square meter, pollegada, centimeter, palmo. *By Tailors and Seamstresses:* Meter, centimeter.

In Machine Shops: Meter, foot, inch, palmo, kilogram, metric ton, gram, liter (*sic*). "The metric system was established by law under the Empire as the only official system. The English system, especially for metal work, is very popular."

In Contracts for Excavation of Ground: Cubic meter, palmo, braca. *In Mines and for Mining Products:* Meter, cubic meter, metric ton, kilogram, gram, oitavo, carat. *In Smelting and for Smelter Products:* Cubic meter, metric ton, inch (*sic*), centimeter (*sic*), kilogram, gram. *Sizes of Pipe for Gas, Water, Sewers, Etc.:* Inch, centimeter, meter for length. "English system chiefly, metric system infrequently." For the measurement of earthen pipes, the internal diameter is usually given in inches. Metal tubing for gas and water is measured by weight, per kilogram. Diameters are usually measured in inches and lengths in meters." "The English measures prevail."

In Ship and Boat Building: Meter, yard, foot, inch. "Generally the English foot; exceptionally the meter." *Marine Measurements:* Marine mile, foot for harbor charts, meter; freight by metric ton, cubic meter, kilogram; depths in meters or feet; knot, league. "English mile for distance; English foot for drafts." "English system." "The nautical mile is most commonly employed; Lloyd's registry is used in calculating tonnage." "Distances, English mile; tonnage, English ton; draft, English foot."

Hay at Wholesale: Arroba, kilogram. *Grain at Wholesale:* Liter, kilogram, prato, cargueiro quarta, alqueire, arroba. *Meat at Wholesale:* Kilogram, arroba. *Root Crops at Wholesale:* Kilogram, arroba, amarrado, metric ton. *Coffee at Wholesale:* Kilogram, arroba. *Milk at Wholesale:* Liter. *Butter and Cheese at Wholesale:* Kilogram, libra, jaca, arroba. *Garden Products at Wholesale:* Liter, kilogram. *Rubber at Wholesale:* Kilogram, arroba.

Railway Tariff for Passengers and Freight (Load and Distance): Kilometer, metric ton, cubic meter. *Loads and Rates for City Transportation:* Kilometer, tonelada, cubic meter, arroba, metric ton, kilogram. *Railway Track Gages and Length of Lines:* Meter, kilometer, centimeter. *Railway Equipment (units used in the construction and repairing of locomotives, coaches, etc.):* Inch, foot, kilogram, meter. "Weight, kilo; measure, English inch."

"The official system of weights and measures, etc., is the metric system. However, the old Brazilian system is still commonly used." According to the Report to the International High Commission on the Metric System in Export Trade, the metric system is "obligatory" in Brazil.

Brazil "adopted" the metric system in 1862.

VALVES AND FITTINGS FOR HIGH HYDRAULIC PRESSURES

Their Design and Maintenance in Operation for Pressures of from 1000 to 8000 Lb. per Sq. In.

BY WM. W. GAYLORD,[1] TORRINGTON, CONN.

With the greater use of hydraulic machines of various sorts as the result of the large manufacture of munitions, a greater interest is to be expected in the design of valves and fittings for such machines. This paper gives the results of my experience, and I have written it largely in the hope that others may be led to publish the results of theirs.

A few years ago when the problem was presented to me of designing a new hydraulic system for a working pressure of 5000 lb. per sq. in., with the probability that this would be increased to 7500 lb. per sq. in., I found there had been very little published on the design of valves and fittings for this pressure, and that the designing formulæ given in standard handbooks were either incorrect or unsatisfactory. The formula most generally given was that of Lamé, based on the maximum-stress theory, which, while correct for cast iron, is not satisfactory for steel. Lanza, in his Applied Mechanics, gives a modification of the Grashof formula based on the maximum-strain theory which I had used before with fair results for steel fittings on lower pressures. I had, however, noticed some unaccountable failures when applied to pipe and fittings using a working pressure of 4000 to 4500 lb. per sq. in.

While studying these failures my attention was called to the maximum-shear theory proposed by Guest, and this seemed to explain most of them. About this time the results of the experiments of Cook and Robertson were published in *Engineering*, December 15, 1911, and after considerable study I became convinced that these offered the best basis for design.

The form in which they give the formula for fiber stress, based on the maximum-shear theory, is

$$\frac{P}{f} = \frac{K^2 - 1}{2K^2}$$

where P is the internal pressure in pounds per square inch, f the fiber stress, and K the ratio of external to internal diameter. This is the equivalent of the usual formula

$$f = P\frac{2}{1 - \dfrac{d_0^2}{d_1^2}}$$

where d_0 is the internal diameter, and d_1 the external diameter.

The results of their experiments show that if a factor of 1.2 were introduced the equation would more nearly represent the actual results, so the formula suggested by them becomes

$$\frac{P}{f} = 1.2\frac{K^2 - 1}{2K^2}$$

By substituting $\dfrac{r + t}{r}$ for K in this formula, the thickness t of cylinder wall of a cylinder of inside radius r becomes

$$t = -r \pm \sqrt{\frac{Pr^2}{0.6f - P} + r^2}$$

From this formula it is apparent that a material having a working fiber stress of 12,500 lb. per sq. in. or less would not be safe however thick the pipe wall. This, of course, eliminates

[1] Chief Draftsman Coe Brass Branch, American Brass Company. Jun.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

bronze, cast iron and semi-steel as materials for making these fittings. After careful consideration of the materials available it was found that cold-drawn seamless steel pipe annealed to give 45,000 lb. per sq. in. elastic limit, and steel castings for fittings giving 30,000 to 35,000 lb. per sq. in. elastic limit, could be obtained, and it was decided to use these.

As the system had no accumulator and therefore was not subjected to severe shocks, a working fiber stress of 0.6 of the elastic limit was used.

The largest pipe in the system was to take the discharge of five pumps, each of 60 gal. per min. capacity, making a maximum flow of 300 gal. per min., but most of the time only three pumps or 180 gal. would be used. In view of this a maximum velocity of 20 ft. per sec. or a usual velocity of 12 ft. per sec. was allowed which required a pipe of 2¾ in. inside diameter. From the above formula the thickness required for a pipe of 2¾ in. inside diameter is

$$t = -1.375 \pm \sqrt{\frac{7500 \times \overline{1.375}^2 \times 2}{0.6 \times 27000 - 7500} + \overline{1.375}^2}$$

$$= -1.375 \pm \sqrt{\frac{28360}{17400} + 1.891} = -1.375 \pm 1.876$$

$$= 0.51 \text{ in.}$$

and for a fitting

$$t = -1.375 \pm \sqrt{\frac{7500 \times \overline{1.375}^2}{.6 \times 19500 - 7500} + \overline{1.375}^2}$$

$$= -1.375 \pm \sqrt{\frac{28360}{8400} + 1.891} = 0.925 \text{ in.}$$

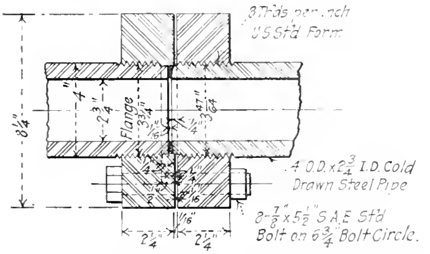

Fig. 1 Typical Flanged Joint for 7500 Lb. per Sq. In.

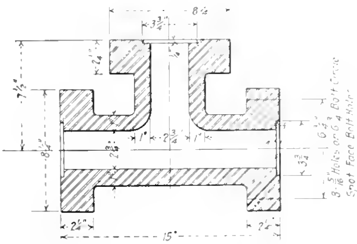

Fig. 2 Typical Flanged Fitting for 7500 Lb. per Sq. In.

A pipe having 4 in. outside and 2¾ in. inside diameters was chosen, as this was a commercial size and allowed the necessary thickness of metal for threading to use in a joint of the type shown in Fig. 1. The fittings were made with a 1 in. wall thickness, the tee shown in Fig. 2 being an example of the type used.

The bolting of the flange was figured by assuming that the full pressure was applied to the area of a circle of the outside diameter of the gasket. In the joint in Fig. 1 this would make a total load on the bolts of $(1.875)^2 \times 3.142 \times 7500 =$ 83,150 lb., which would require eight 1⅜-in. bolts if U. S. standard bolts were used, allowing a working fiber stress of 10,000 lb. per sq. in. This would have taken a flange about 11 in. in diameter and would have made the piping very hard to install in the limited space available, so it was decided to use bolts made to the S. A. E. or, as it was then known, the A. L. A. M. standard. Using a working stress of 22,500 lb. per sq. in., this allowed the use of eight ⅞-in. bolts in an 8¼-in. flange. This is open to the objection that a careless mechanic may replace these special bolts with standard bolts and thus cause the failure of the joint, but there has been no trouble from this cause.

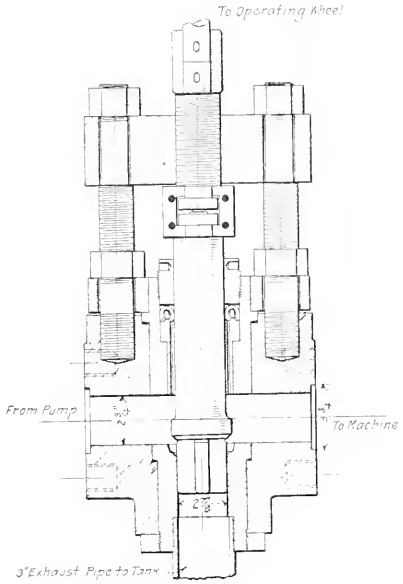

Fig. 3 Operating Valve for 7500 Lb. per Sq. In.

When the piping was installed, some of the gaskets were of soft copper and the rest of red fiber, but experience has shown red fiber to be more satisfactory as the copper soon hardens and a slight water hammer will often start the joints leaking, while the red fiber does not give this trouble.

The system was to supply three machines from a group of five pumps, and the piping was to be so arranged that the large machine, which was to use pressures up to 7500 lb. per sq. in., could be operated with any or all of the pumps while the other two machines were to be operated with one or two pumps each, but the connections were to be so made that any pump could be connected to any machine. This was done by using a manifold tee on the discharge of each pump with a valve connecting to each pipe line.

The valves originally put in were of two types: one a wedge gate valve with cast-steel body and hard bronze wedge, the other a stop valve of the balanced type having cast-steel body and bronze plunger. The gate valves proved impracticable as the bodies could not be made sufficiently rigid to prevent distortion of the seat and the starting of a leak which would

grow very rapidly because of the cutting action of the water. The other valves were more satisfactory and could be kept fairly tight by frequently dressing the seat and plug; but it was found more satisfactory to use blank flanges and pipe spools in place of the valves to make necessary changes in connections.

The machines were in effect single-acting presses in which the ram was returned by an auxiliary low-pressure system. The main operating valve therefore became a bypass valve which was closed to drive the ram forward and opened to allow the ram to stop and be returned. The valve in Fig. 3 was chosen for this place and was first made without the loose connection shown in the stem, but it was found very hard to open it after it had been shut tight, so the connection was added and this difficulty overcome. Experience had shown that the rather difficult to build, it has proved very satisfactory.

On a smaller press having three double-acting cylinders designed to operate in regular sequence, a multiple valve of the semi-balanced spring-closed type was used, having the individual valves opened by bell-crank levers moved by face cams mounted on a common shaft. The cams were so arranged that rotation in one direction would cause the cylinders to operate in the proper order. The valve was so designed that when open the area through the seat was greater than around the stem.

In designing valves and fittings for service on accumulator systems I have found that it is usually the severity of the water hammer rather than the actual pressure that determines the strength required and that in laying out such a system all possible care should be used to avoid trouble from this source.

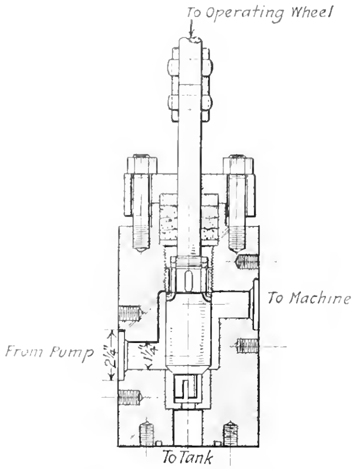

FIG. 4 OPERATING VALVE FOR 5000 LB. PER SQ. IN.

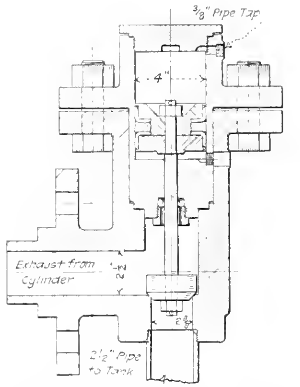

FIG. 5 CAST-STEEL EXHAUST VALVE USED TO REPLACE VALVE IN FIG. 6

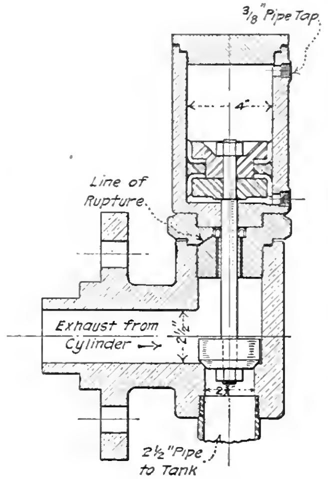

FIG. 6 EXHAUST VALVE FOR 5000 LB. PER SQ. IN.

form of seat used with the beveled recess for the plug would last much longer than if the valve had a flat seat.

This system has been in use five years, often with a working pressure of 8000 lb. per sq. in. for short periods, with no failures, and with the exception of the valves mentioned has given good satisfaction.

On two similar systems more recently installed for operating pressures of from 4000 to 5000 lb. per sq. in. the same type of pipe and fittings has also been used with success. The operating valves furnished for these systems were made as shown in Fig. 4 and proved unsatisfactory, as the water pressure on top of the plug held the valve closed so that it was almost impossible to open it. These were replaced by valves similar to Fig. 3, which are working satisfactorily.

These machines had an exhaust valve as shown in Fig. 6 which returned the water direct from the main cylinder to the tank on the return stroke of the ram. These gave much trouble by the intermediate piece between the valve body and operating cylinder breaking through as indicated. This in two cases blew the operating cylinder entirely off the valve body. Two of the valve bodies also failed by splitting. In view of this and the fact that a leakage through the U-leather packing might also blow the operating cylinder off, it was decided to redesign this valve, using a cast-steel body and cylinder arranged to eliminate these faults. Fig. 5 shows this valve, and although it is

However, as the severity of water hammer in a new system can never be exactly determined before it is in operation, I have used the designing formula given in the first part of this paper, with a working fiber stress of one-third to one-half the elastic limit of the materials employed, depending on the probable severity of shock from this cause. This I have attempted to check by figuring the rise of pressure to be expected due to the inertia of the moving parts of the accumulator if all operating valves should be closed at the same time. This is done by assuming the ram of the accumulator to be coming down with a maximum velocity and figuring the force necessary to cause a negative acceleration sufficient to stop it in an assumed minimum time of closing the valves. This at best can only be a rough check but has proved sufficient in several cases. The piping should be so supported and anchored that water hammer will not cause any considerable whip, as this is the usual cause of broken fittings and leaking joints.

The valve most used to control single-cylinder machines like draw benches on an accumulator system is a combined throttle and reversing valve, while the valves for multi-cylinder machines are too numerous and complex to describe in this paper; but the principles used in their design are the same as for the valve already described, except that greater care must be exercised to prevent too rapid opening and closing and consequent destructive water hammer.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, Including Abstracts of Articles in Current Technical Periodicals

Italy to Have Aerial Laws

THE Italian Government has just completed the draft of a series of laws covering aerial navigation. First of all, the law fixes the technical names to be used in designating the more important aspects of aerial navigation. All aircraft, whether airplanes or dirigibles, will be known under the general name of aeromobiles. Aeriat ports will be the name applied to the regular places for landing and departing, while refuge ports will be the name applied to those landing places where the aerial craft can put in in case of accident.

The law provides that regular aerial ports are to be equipped with very much the same facilities as are to be found in any great seaport for the landing, unloading, repairing and taking on of cargoes.

Special articles provide for what an aeromobile must do if obliged to land in other than a regular or refnge aerial port.

Special provisions govern the zones of altitudes in which the aeromobiles must navigate to prevent collisions and other accidents.

For reasons of national defence, there is an article prohibiting aeromobiles from flying over forts and other military and naval defences. The proposed laws would prohibit transportation by aeromobiles of inflammable matter, explosives and other kinds of merchandise that might endanger the aircraft and other property in case of accident.

Other articles provide that all aeromobiles must be registered in the national registry of aircraft; that each aeromobile must have a government certificate of its navigability: that there mnst be officers of recognized competency aboard, and that each aircraft must carry certain official documents.

The proposed code, in all probability, will be made law at the coming session of Parliament. (*The Evening Sun*, New York, Oct. 4, 1918, p. 20)

New German Textile Substitutes

In THE JOURNAL for July (p. 581) reference was made to a German textile substitute, a wood-pulp fiber called "cellulon." Further information regarding this and other substitutes is given below.

Paper yarn, which has been used in the manufacture of sacks, carpets, beltings, and like articles not washable and of a coarse fabric, has not yet been found suitable for clothing. From cellulon, however, a yarn is obtained somewhat better than paper yarn, but still not fitted for anything but coarse fabrics.

Another product, "Stapelfaser," seems to promise better results. In the manufacture of paper yarn the cellulose fiber is cut off when the paper is cut into strips for the spinning machines. Efforts are now being made to secure longer fibers from cellulose. In the manufacture of Stapelfaser the cellulose treated with certain chemicals is dissolved to a jelly-like mass, which is pressed through very fine strainers, thus producing fine fibers. These fibers are then twined together into coarser threads. The thread is rolled up and cut into pieces from 4 to 5 cm. (= 1.57 in. to 1.97 in.), which are put through a drying process, during which the fibers part from each other, leaving sufficiently long and fine threads. This method of manufacture is somewhat similar to the one used in the manufacture of artificial silk.

Stapelfaser is claimed to replace cotton and wool, except that it is not as washable. It may be washed, but when wet must not be pulled. As soon as dry it is just as good as before. However, if, when weaving, a small portion of wool or cotton is inserted, a full washable fabric is obtained.

The above facts are from the *Frankfurter Zeitung*, which journal, however, claims that the textile question is not yet fully solved. It states that the production of clothes from Stapelfaser has already been started at several factories in Germany, but that the products have been taken by the military authorities for the needs of the army. Even if the method is technically finished, production is dependent upon the supply of raw materials and mainly chemicals. Both the raw materials and the chemicals necessary are available in Germany, but not in sufficient quantities.

The Textile-Industrie A. B., in Barmen, has succeeded in obtaining a product from cellulose yarn which, without any dressing, can replace leather and from which shoes are said to have been successfully made. (*Commerce Reports*, no. 233, Sept. 23, 1918, p. 1114)

War Department Committee on Education and Special Training

The Committee on Education and Special Training of the War Department has issued a special bulletin on programs in engineering which is intended to indicate how existing courses at schools may be modified by eliminations and condensations so as to meet the needs of the present emergency.

A significant feature of the programs is the inclusion of the subject of war issues in two terms. The approved course in mechanical engineering is as follows:

MECHANICAL ENGINEERING

	Hours per week

Shipyards and Shipways

When the present Shipping Board began its work, in August 1917, there were only 61 shipyards in the United States. There were 37 steel shipyards with 162 ways. About three-quarters of their capacity had been preëmpted by the naval-construction program, while private orders overflowed the remaining ways. In the 24 wood shipyards there were only 73 ways.

The largest shipyards in the world in September 1918 are those of the United States. The Clyde River, in Scotland, historically famous as the greatest of all shipbuilding localities, is already surpassed by two shipbuilding districts on the Atlantic coast and by two on the Pacific coast—by Delaware River and Newark Bay in the East and by Oakland Harbor and Puget Sound in the West. One yard, Hog Island, on the Delaware, is equipped to produce more tonnage annually than the output of all the shipyards of the United Kingdom in any pre-war year. It has 50 ways.

There are now 203 shipyards in the United States. The list comprises 77 steel, 117 wood, 2 composite and 7 concrete shipyards. Of these, 155 are completed, 35 more than half completed, and only 13 less than half completed. The great plant at Hog Island is 95 per cent completed—built in one year on a site formerly a swampy marsh.

Every month of the past year has added to the number of American shipways, until today the impressive total is 1020—more than double the total of shipways in all the rest of the world. Of the 927 shipways that are for the Emergency Fleet Corporation of the Shipping Board, 810 are listed today as completed, and only 117 are to be added. There are 410 completed ways for the construction of steel ships, 400 completed ways for the construction of wood, composite and concrete ships. (*Shipping Facts*, issued by U. S. Shipping Board)

Fourth National Exposition of Chemical Industries

The Fourth National Exposition of Chemical Industries, Grand Central Palace, New York, September 23 to 28, 1918, was signalized by the gathering of a notable body of men engaged in the various industrial applications of chemistry. Various addresses were made comprising a series of symposiums devoted to the consideration of the development of the chemical industries in the United States, notably since July 1914.

Tons of machinery and material were exhibited, transported in spite of present war difficulties, which tangibly attested America's approach to chemical leadership. The achievements in the production of dyestuffs and explosives and acids; the independence of the potash industry, of vital importance to the United States; the wonderfully encouraging and typically American progress of the ceramic industries; the new achievements in metals and alloys in which we have long held high rank; and the growing importance of organic chemistry in the arts and industries, were abundantly evidenced by the varieties of new devices and methods exhibited.

The Chemical Warfare Service of the United States Army displayed the developments in chemical warfare. Originals and photographs of various types of masks were shown. The new American type was also displayed, and its future use in mines was clearly indicated. Offensive gas warfare was represented by specimens of shells and grenades of many sorts. They are designed for the various different types—sneeze, mustard, lethal, phosphorus (for incendiary work and to produce white smoke) and others. An oval form of shell was shown that may fall into any position without becoming a "dud"—a shell that fails to explode.

Copies of rules and general orders relating to chemists and engineers in essential industries and providing for the allocation of enlisted men were distributed by the chemical-warfare exhibit.

New York Section of American Society of Refrigerating Engineers

At the meeting of the New York Section of the American Society of Refrigerating Engineers, held on September 18 at Machinery Club, New York, Charles N. Neeson gave an informal talk on his experience with electrically operated high-speed refrigerating machines. He stated that these machines are started much quicker and easier when the bypass as well as the suction and discharge valves are closed, especially when the back pressure is high. It is necessary to shut the discharge valves when starting on account of leakage through other valves. With the introduction of the high-speed ammonia compressor, the selection of proper valves giving large clearance to the compressors is essential for the successful operation of the machines. In the plant of Mr. Neeson's company, with 18 cans per ton of ice, 35 kw-hr. per ton was achieved, and for the summer conditions, 22 kw-hr. per ton. With a cooling-tower plant 32 kw-hr. per ton was had, and for summer conditions, 12 cans per ton, 60 kw-hr. per ton of ice. The compressors have center ports and the indicator diagrams showed a 5-lb. drop in the suction pressure, with 20 lb. excess above the head pressure at the end of compression. There was about 25 per cent reëxpansion with the high head pressure.

F. L. Fairbanks said that on the whole the tendency was to give high-speed compressors too little total valve area. There is a tendency on the part of the operator to make plate and feather valves give from two to four years' service, whereas a feather or a plate valve should be changed every six months to avoid serious recesses in the valve seats. In reference to the effect of inertia of the reciprocating parts, Mr. Fairbanks said that with his 1000-ton compressor, which has a 24-in. shaft, 28 ft. long, running at 45 r.p.m., the machine could be run with the caps and quarter-boxes out of the bearing, but at 50 r.p.m. the 150-ton shaft was lifted off the bottom bearings owing to the inertia of the pistons and other reciprocating parts.

The meeting manifested an anxious interest in the question of flywheel effect for high-speed compressors, and particularly for the compound type driven with synchronous motors. Experience seems to show that where there are a number of these machines in one plant, any one running singly gives no trouble in the way of regulation, but when two or more of appreciably different capacities are in parallel, considerable trouble is experienced in regulation. (From account of the meeting given in *Power*, October 1, 1918)

Western Society of Engineers

A meeting of the Western Society of Engineers was held in Chicago on September 23, under the auspices of the hydraulic, sanitary and municipal section. W. G. Edens, President of the Illinois Highway Improvement Association, in a paper on Illinois roads, explained the need for improved highways and, referring to the proposed $60,000,000 bond issue to be voted on November 5, he laid stress on the part engineers can play in promoting this program for after-the-war work, as under the terms of the proposed issue the bonds are not to be sold until after the war.

Engineering Materials

The Effect of Cold Work on Copper, W. E. Alkins. An investigation to determine whether any quantitative relationship exists between the amount of cold work done upon the metal and the magnitude of the change in its properties.

In particular, an account is given of an inquiry into the change in tensile strength of copper in the form of wire as it is progressively hardened by cold drawing in the ordinary way.

Copper was chosen as the experimental material for three reasons: (1) It appeared to afford an example of a simple metallic system which is supposed to undergo no definite thermal change between its melting point and the ordinary temperature (though an allotropic modification of copper with the transition point at about 70 deg. cent. is claimed to exist by Cohen); (2) copper shows the hardening by plastic deformation very well; and finally, in this particular instance, it was most readily obtainable by the author in the required form and of superior purity, in particular, 99.92 copper with the remainder consisting of oxygen with a smaller amount of arsenic.

The author gives a brief discussion of the previous work by Thomas Bolton, A. P. Trotter and D. R. Pye. Of these Trotter concluded that there was a linear relation between the tensile strength and the diameter, and suggested that the tensile strength might be expressed by a formula of the type

$$T = a - bD$$

where T is tensile strength in tons per sq. in., D diameter in inches, and a and b are constants.

The method of carrying out the tests and taking the various measurements is described briefly and the results given in the form of tables and curves. The results of tensile tests give a smooth curve for the tensile strength against diameter of sectional area, but at the same time show conclusively that the effect of a certain amount of cold work at any stage is intimately connected with the previous history of the metal.

From this point of view the curve of Fig. 1 is of interest. This curve showing the variation of tensile strength with sectional area consists of two rectilinear portions, AV, CD, connected by a smooth curve BEC. This curved portion shows only a point of inflection at E, and not a maximum and minimum.

The portion AB corresponds to the equation:

$$T = 31.6 - 67A$$

where T = tensile strength in tons per sq. in;
A = cross-sectional area in sq. in.

The upper rectilinear branch CD corresponds to the equation:

$$T = 30.83 - 82.66A$$

The curved portion BEC agrees very closely with the expression:

$$T = 23.2 - \sqrt{A - 0.107}$$

but while the form of this portion is of the first importance,

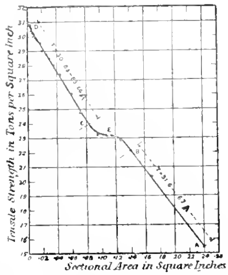

Fig. 1 Curve Showing Variation of Tensile Strength with Sectional Area

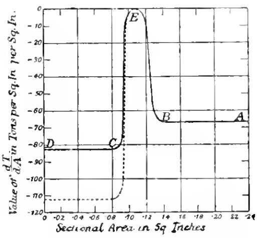

Fig. 2 Curve of Differential of Curve of Fig. 1 with Respect to Cross-Sectional Area

the corresponding mathematical function is only of secondary interest.

Significance of the Curve of Fig. 1. Differentiating the curve of Fig. 1 with respect to area (A), we have:

Over the portion AB, $\frac{dT}{dA} = -67$; from B to E the value of $\frac{dT}{dA}$ changes from -67 at B to 0 at E; from E to C the value of $\frac{dT}{dA}$ diminishes from 0 at E to -82.66 at C, and over

the branch CD, $-\frac{dT}{dA} = 82.66$ (*cf.* Fig. 2, which is lettered to correspond with Fig. 1).

Thus, from A to B the tensile strength increases at the rate of 67 tons per sq. in. for a reduction in area of 1 sq. in., while from C to D the rate of increase is 82.66 tons per sq. in. per sq. in.; the rate diminishes from B to 0 at E, and increases again from E to C; the curve shows no discontinuity, and at no stage is there a simultaneous diminution in sectional area and in tensile strength. From the foregoing considerations it appears that in the drawing of copper the phenomena which present themselves are not of that simple nature which the amorphous theory would lead one to expect.

The variation of several other physical properties of the metal was investigated and such properties as density, elongation, scleroscope hardness, and so on, were all found to change in a way similar to tensile strength. The following tentative explanation of the above results has been suggested: When copper is subjected to cold work by drawing through dies the first change which occurs is allotropic in nature. After this change is complete, that is, presumably when the whole of the metal has undergone transformation, a second change sets in which may be regarded either as allotropic or as explicable on the lines of the amorphous theory, and of the two possibilities the latter appears to be the more probable. (Paper read before the Institute of Metals on September 10, 1918, abstracted through *Engineering,* vol. 106, no. 2770, September 13, 1918, pp. 282-285, 4 figs., *eA*)

THE INFLUENCE OF SOME ELEMENTS ON THE TENACITY OF BASIC STEEL, Andrew McWilliam. The writer proposes a new formula for calculating the maximum load from the composition of steel. The first formula given for basic steel was

$$\text{Maximum load in lb. per sq. in. of original section} = 38{,}000 + 800\text{C} + 100\text{Mn} + 1000\text{P}$$

in which the carbon, manganese and phosphorus are expressed in units of 0.01 per cent. It was found, however, that under certain conditions this formula did not give correct results. Thus, around 0.2 per cent carbon the results were correct, but at 0.5 per cent carbon they were too low. It was thought then that as the carbon would be present in the form of pearlite to which the added strength was due, the more pearlite present the greater effect the carbon would have per unit on the tenacity of the mass. Further, as the manganese influenced the nature of the carbon, its influence would increase with increasing proportions of pearlite. Another calculation was made with the result that the maximum load in pounds per square inch of original section is expressed by the following formula:

$$\text{Maximum Load} = 38{,}000 + [800 + 4\ (\text{C} - 20)]\ \text{C} + 120\text{Si} + [100 + 2\ (\text{C} - 20)]\ \text{Mn} + 1000\text{P}$$

This formula has stood the test of trial quite well and even with the higher-silicon shell steels has given good results.

To check the correctness of this formula the writer compares the results derived by this means with those obtained experimentally by Arnold and shows that the two are in close agreement. (Paper before the September 1918 Meeting of the *Iron and Steel Institute,* abstracted through advance copy, 13 pp., 3 figs., 5 tables, *eA*)

Internal-Combustion Engineering

DIESEL ENGINES FOR MOTOR VEHICLES. Notwithstanding the great amount of work devoted to this purpose no one has succeeded in developing a Diesel-engine drive for motor vehicles.

This is due to the fact that no small high-speed multiple-cylinder Diesel engines have yet been constructed, and this again is mainly due to the difficulty of building a reliable small pump that would deliver air at about 100 atmos. pressure and would be easy to operate notwithstanding its many valves and regulating devices.

Austrian Patent No. 72356 describes an attempt to inject the fuel into the combustion chamber at variable pressure, but with a constant position of the needle valve.

With such an arrangement it was found that it is quite feasible to introduce into the cylinder the exact predetermined amount of fuel and to regulate it at will. The experimental installation consists of a three-cylinder, two-stroke-cycle engine with cranks at 120 deg. To use the engine for motor-car driving it is necessary to provide two steel flasks filled with air at 70 atmos. pressure. One of the flasks serves to start the engine, while the other delivers air for fuel injection. When the engine is running it makes its own compressed air. The flasks hold 1400 liters of free air each and can easily be carried on the car. For purposes of starting the air pressure is reduced to 10 atmos. (the original article does not state whether gage or absolute pressure is referred to).

The fuel injection occurs during 25 deg. of the crank rotation. In the experimental engine exhaust slots are provided along the entire circumference of the cylinder, but the scavenging air enters only through its own valve in the cylinder head. It is the view of the inventor that slots for the admission of scavenging air should be avoided, because at great speed a thorough scavenging by means of slots cannot be secured, and, further, if slots are used both for the scavenging air and for the exhaust, unequal expansion of the cylinder walls is apt to occur.

The scavenging valve opens after the piston has uncovered half the height of the exhaust slots and therefore permitted a complete expansion of the gases of combustion to occur. The scavenging air enters the cylinder at a pressure of 0.34 atmos. and an excess of 50 per cent of scavenging air is provided. The air valve remains open at exactly 90 deg., or one-fourth of the crank revolution. The exhaust slots remain open for 110 deg. The scavenging air is produced by the engine itself, an expansion piston being added to the working piston for this purpose. The air of combustion is compressed in the cylinder at 35 atmos. and is thereby raised to 580 deg. cent.

For the sake of safety the engine is driven by kerosene and for its injection into the cylinder an air pressure of from 40 to 70 atmos. is needed. This is obtained by means of an air compressor driven by the engine. The fuel flows to the pump automatically. The pump is driven from the engine at a speed reduction of 1:10 corresponding to the air-compressor drive. The fuel pump takes up the fuel by suction and forces it into the air container, having a capacity of about 1 liter, in which there is air compressed to from 40 to 60 atmos., but the fuel pump has absolutely nothing to do with the engine governing. The overfilling of the container is prevented by a simple governing device which acts on the suction valve of the fuel pump by the pressure in the air container.

The working cylinders are made of steel and form a unit with the scavenging air cylinders located underneath. The use of steel results in a considerable saving in weight, as well as a better cooling than would be the case with cast iron.

The air compressor is so large that the supply of starting air can be replaced in any case within a quarter of an hour after starting. The compressed air which forces the fuel into

the cylinder either does not reach the combustion chamber at all, or else in very small amounts. In this way but very little injection air is used and, therefore, the air compressor can be quite small and can be run at the low speed of 120 r.p.m., which materially increases the reliability of operation. While in an ordinary Diesel engine 8 cu. m. of injection air would be consumed, the new injection method permits using the same amount of air as of fuel, or at most 0.088 cu. m. The air compressor is single-acting two-stage and compresses in the first stage to 8.4 atmos. and in the second stage to 70 atmos.

The fuel valve has a needle in constant position. The fuel goes into an annular distributing chamber and is given a rotary motion in its helical passages. From this chamber it enters the combustion space through the fine holes in the nozzle, which is shaped like an injector. By the injector action of the fuel jets a strong turbulent motion of the air is created in the combustion chamber which leads to a good mixture of the fuel with the compressed air in the cylinder. Since no injection air is allowed to enter the cylinder, the undesirable cooling of the mixture is avoided. It is claimed that extensive tests have been made with the new system of fuel injection in order to determine whether the fuel chamber is necessary for governing the engine. These tests have also shown that the atomization of the fuel is perfect and that no drops are formed from the fuel present in the nozzle. In order to determine the quality of atomization the fuel was allowed to discharge into the atmosphere and the kerosene mist was ignited for experimental purposes. It was found that when the nozzle was kept open for some time the length of the flame varied with various air pressures from 1.5 to 2.5 m.

In the original article a diagram is given showing that the amount of fuel ejected is proportional to the air pressure, though at higher pressures the increase in the ejection of the fuel is not as great as with smaller pressures. This may be explained by the fact that at higher pressures and greater velocities in the nozzle passages the coefficient of friction increases more rapidly. (*Dieselmaschinen für Fahrzeuge, Allgemeine Automobilzeitung,* nos. 29-32, abstracted through *Dinglers Polytechnisches Journal,* vol. 333, no. 4, February 23, 1918, pp: 31-32, 1 fig., *e*)

1500-Hp. Gas Blowing Engine. Very brief description, with two pages of illustrations, of a gas engine and blower recently built in England for the Partington Steel and Iron Company. The engine is of the 6-crank vertical tandem type, and is rated to develop 1500 b.hp. on continuous load at 200 r.p.m. working on blast-furnace gas of 90 to 100 B.t.u. per cu. ft. The load can be increased by 10 to 20 per cent for short periods without overheating. A special speeder gear device is fitted to enable the speed to be reduced to as low as 120 r.p.m. (*The Engineer,* vol. 126, no. 3271, September 6, 1918, p. 207, and 2 pp. of illustrations, *d*)

Machine Parts

Disastrous Flywheel Explosion at Chicago. At 2.00 p.m. on the afternoon of September 19 a large flywheel exploded in engine room No. 1 of the Chicago Coated Board Company with considerable damage to life and property. The engine to which the flywheel was attached was a 24-in. by 42-in. 500-hp. simple Corliss making 108 r.p.m.

The flywheel had six spokes, had been cast in halves and bolted together at the hub and rim. The engine was thoroughly protected against overspeeding by a flyball governor equipped with the usual safety stop and by an additional engine stop arranged to be operated mechanically and electrically. Evidence indicates that the accident was not caused by overspeeding, and further, the load was constant and the speed normal.

The engineer's attention was first aroused by the noise of escaping steam and immediately after by the commotion caused by the flying parts of the wheel. The flywheel had been broken to bits, there being only two large pieces, one containing two spokes and the intervening rim, and the other a single spoke. Curiously enough, the engine to which the ruptured flywheel belonged was not damaged in the least.

The theory of the accident is that a small part of the rim first let go, severing the steam pipe, as the noise of escaping steam first heard would indicate. This so badly unbalanced and weakened the wheel that it could not withstand the strain imposed by the peripheral velocity of 4920 ft. per min.

In cast-iron rims of the section adopted for this wheel, namely, one having unequal thicknesses of metal, severe internal stresses may be set up by uneven cooling in the mold. While there were no signs of blowholes or other defects, the design of the wrecked wheel is very weak. It was made in two

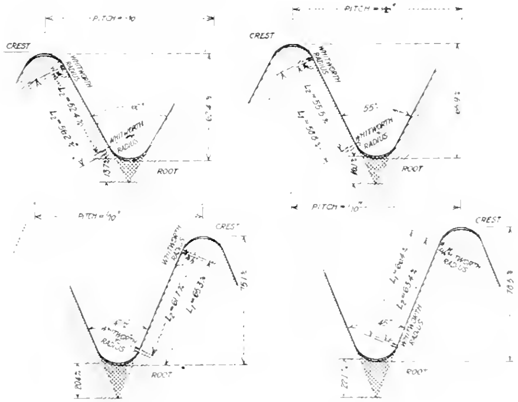

Fig. 3 Comparison of Screw Threads of Various Angles

parts with flanged and bolted rim joints located between the arms, and in addition had a belt wheel which further weakened it to a point where, according to Kent, the joints averaged only one-fifth of the strength of the rim.

The weight of the bolt flanges was concentrated in the middle of the arc between the arms, which is a bad feature of design and may account in part for the low strength allowance. Acting on the weakest part of the rim, the weight would tend to bow outward the arc of the rim between the spokes. The force would be greater when the joint was not supported by the belt, so that there would be a varying strain to fatigue and crystallize the metal in the rim between the joint and the arm. (*Power,* vol. 48, no. 15, October 8, 1918, pp. 516-519, 6 figs., *d*)

The Relation of Screw-Thread Angles to Other Functions, H. J. Bingham Powell. The writer advocates the adoption of the Whitworth form of thread as an international standard.

The radius of the Whitworth screw is said to come under the designation of a "natural" one, because many years of experience in making it show that it has about the least radius at which the tool will maintain a stable cutting point. In fact, the writer states that even in the United States he has found

the same to be true from investigations on the radii of the roots of the U. S. standard form of bolts cut by dies which were nominally supposed to have a flat root. The flat top (such as used in the U. S. S. thread) is about the worst for a tool that can be imagined, as apart from the corners rapidly disappearing by abrasion, they become overheated and brittle and fall off. Thus, the rounded top and bottom for a thread is a practical necessity, while the U. S. S. flat top and bottom are impracticable and consequently hardly ever obtained in ordinary commercial work with taps and dies.

Fig. 3 shows a comparison of screw threads of various angles. In drawing up the diagrams the author gave the "natural" Whitworth rounding at the crest and root of the threads of the several angles, since that is, in his opinion, the shape they will have as made, whether the maker set out to produce the flat U. S. S. form or the rounded root of sharp radius striven for in the international type.

In fixing on a desirable thread angle the correction necessary to the pitch diameter for any error of lead in the screw must be taken very seriously into consideration. This correction is 10 per cent greater for the Whitworth, 31 per cent greater for the British Association and 43 per cent greater for the 45-deg. angle than the correction necessary for a 60-deg. thread. This increase for the 45-deg. angles is so large as to make this angle impracticable.

The author therefore recommends for consideration as a standard international thread the Whitworth form with its "natural" rounding at the crest and root and much greater space at the root available for tolerances as compared with the U. S. S. form. (*American Machinist,* vol. 49, no. 13, September 26, 1918, pp. 571-573, 1 fig., *cg*)

Machine Shop

Casting Rings in Centrifugal Machine, E. F. Cone. Description of new process for casting piston rings and the apparatus used therefor.

In The Journal of October 1916 (p. 831) there was described a method of making cast-iron pipe centrifugally, invented by a Brazilian engineer, D. Sensaud de Lavaud. The present process is the further development of the same method and, according to the description, is remarkable both for the extremely rapid production as compared with the labor employed and for the properties of the rings themselves. As to production, one unit with about eleven men and boys delivers 18,000 to 20,000 rings a day.

The process of manufacture is comparatively simple. It consists in introducing into a rapidly revolving permanent metal mold a definite amount of hot metal of proper composition, which is immediately thrown to the outer surface of the revolving mold. There it quickly cools and assumes its definite shape. After that the ring is removed and annealed and then the inner rim of the ring is ground on a special machine.

The casting machine and the special re-assembling machine for the molds are described in the original article. An interesting apparatus has been devised for annealing the rings. It consists of a cylinder confined or suspended perpendicularly within a large iron chamber. At a certain section it is heated to the required temperature by means of an oil burner extending inside the outer casing and playing on the cylinder, the degree of heat of the rings for annealing being regulated by a pyrometer. The diameter of the pipe is about that of the rings to be annealed, thus keeping the rings to their exact shape. The heat treatment is nearly automatic. The rings are fed in at the top and as they pass down they reach the proper temperature of 1900 deg. fahr. and finally pass out at the bottom properly annealed. It is stated that this device can treat 20 rings a minute, or about 1200 an hour.

Information on the properties of the metal in the ring is based on tests made for the inventor at Columbia University, New York. From these tests it appears that the machine-cast rings had a tensile strength of 61,400 lb. per sq. in., which may, however, have been partly due to the very small size of the specimens. The ultimate resilience in compression was found to be 19.28 in-lb. and it was further found that the machine-cast rings have a very pronounced elastic limit well below the ultimate strength, which would indicate a considerable amount of uniformity in the structure of the metal. Micrographic investigation has shown the graphite to be distributed in a fine condition and the entire crystalline formation appears to be homogeneous. (*The Iron Age,* vol. 102, no. 14, October 3, 1918, pp. 801-807, illustrated, *d*)

Marine Engineering

The Yarrow Anti-Submarine Smoke System. Description of a system developed for application to merchant vessels with the view to reducing the visibility of the vessel.

It has been found that a steamer with the usual type of funnel emitting a column of smoke to a height of 150 ft. would be visible to an observer on a submarine 17.4 nautical miles away. The freeboard of the steamer being taken at 33 ft., the elimination of her smoke column would result in her remaining invisible to the submarine at all distances greater than 10.17 nautical miles. This means that with the smoke column emitted in the usual way, the area within which the steamer is visible from the submarine is 950 square miles, while with the smoke column eliminated this area is reduced to 320 square miles.

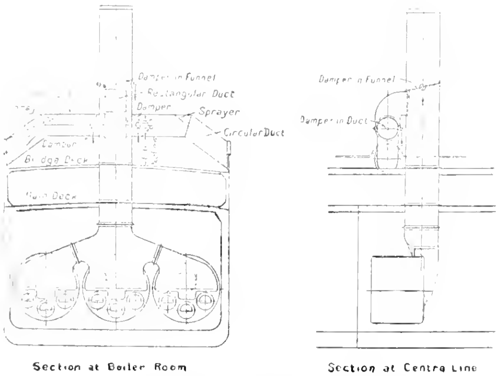

Fig. 4 Duct and Damper Arrangement of the Yarrow Anti-Submarine Smoke System

As shown in Fig. 4, in the Yarrow anti-submarine smoke system means are provided for diverting the smoke and waste gases out of the funnel into a duct or ducts leading to the sides of the ship and ejecting them on to the surface of the water by means of a water spray fitted within the ducts. The object of the water spray is to cool the gases so as to cause them to fall to the sea water level instead of rising again immediately after they leave the duct, and, further, to absorb a large proportion of the solid particles of carbon in the smoke, thus reducing its blackness and therefore its visibility.

In actual use, the smoke is said never to rise above the level of the bridge, while the hot gases cause part of the water of the spray to become steam, with the result that the smoke issuing from the side ducts is quite similar in appearance to that emitted by a locomotive, and is black only for a minute or two after the furnace fires are stoked afresh.

Actual experience at sea has shown that the draft induced by the water sprays is much superior to that obtained in the usual way from the funnel, and therefore the control of the air supply to the furnace is improved.

As shown in Fig. 4, a damper is provided in the funnel and another in each of the side ducts. The handles of the dampers are interconnected in such a way that all three dampers cannot be opened at the same time. In general, it is intended that when the system is in use the funnel damper should be closed, the damper in the duct on the leeward side of the vessel opened and the damper on the other duct closed. Different conditions may, however, require a different system of operation.

The water for the sprays is supplied by a pump in the engine room capable of delivering a jet at a pressure of 180 lb. per sq. in. The sprayer when properly regulated should produce a cone of spray, the edges of which should just touch the outlet edges of the duct and also sides of duct outlet. This condition is quite important. (*The Engineer*, vol. 126, no. 3272, September 13, 1918, pp. 218-219, 8 figs., *d*)

MANUFACTURING EAGLES AT FORD'S SHIPYARD, Chas. Lundberg, Mem.Am.Soc.M.E. Description of the Ford submarine chasers and their method of manufacture as carried out in the Ford plant on the River Rouge at Detroit.

The entire plant was built in less than five months and consists of a main structure 350 ft. by 1700 ft., of steel and glass with composition roof; a fabricating shop 155 ft. by 450 ft., to which 150 ft. more is being added; a great fit-out building, a transfer table 202 ft. wide for the transverse movement of completed hulls, and a hydraulic launching machine which gently and always under full control lowers the ship into the water.

The boats are assembled in a great building, 21 of them being under construction at one time.

Each boat is assembled on a carriage supported by car wheels, there being 12 trucks, each with four wheels under each carriage. The building of the boat comprises seven groups of operations and they are so timed as to be finished simultaneously. When a ship moves out to the transfer table on its way to launching those behind it move up in position for the next set of operations. Briefly outlined, these operations are as follows:

No. 1: Keel laid and bulkhead collars placed, also some of the floor beams, part of the longitudinal bulkheads, center and inner bulkheads. (Incidental riveting, of course, is a part of each series of operations, likewise reaming rivet holes and some welding.)

No. 2: Floor built and frames (of which there are 113) erected the entire length of the boat; athwartship bulkheads, liners, keelson and floor stringers. Engine room, tank plating, platform deck beams placed fore and aft.

No. 3: Forward deck plating, outside and after-deck plating, gunwale bar and collars, main deck beams, stanchions, engine and boiler room, rudder brackets.

No. 4: Remainder of platform deck plating; bulkheads from platform to main deck, windlass and steam-engine foundations, signal room.

No. 5: Deck bars and fittings, scuttle and manholes, watertight floors and calking.

No. 6: Forward and aft deck houses, breakwater, charthouse, strut and stern bearings, bilge and drain piping, oil compartment tunnel.

No. 7: Seacock and strainer installation, steering gear and stuffing box, steering engine and anchor, ladder stairways, oil pumps, auxiliary pumps and air compressors. Installation of shaft and propeller. Riveting, welding and calking completed, all compartments air-tested, painting and inspection completed.

An interesting part of the original article is devoted to the method of handling labor. (*The Iron Age*, vol. 102, no. 12, September 19, 1918, pp. 679-684, illustrated, *d*)

Motor-Car Engineering (See also Internal-Combustion Engineering)

HEAVY-OIL-BURNING ARRANGEMENT FOR MOTOR CARS. Description of an arrangement invented by F. A. Wilkinson to burn tar oil on an ordinary automobile.

The car is started on coal gas, which may be replaced by gasoline. When the heavy oil is first switched on and after the

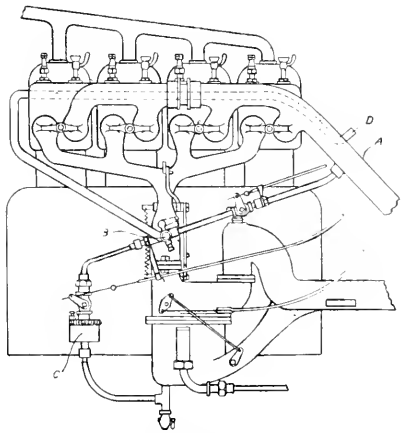

FIG. 5 WILKINSON HEAVY-OIL-BURNING ARRANGEMENT FOR MOTOR CARS

car has been standing there is a certain amount of temporary smoke emission and the fumes from the exhaust are decidedly pungent, but the car is said to run with perfectly regular firing and to pick up well.

Fig. 5 shows the arrangement used. The original carburetor of the car is retained, but additional pipes are installed. The first of these is a small pipe A leading from the exhaust pipe and admitting exhaust gases through a valve B into the inlet pipe just above the carburetor. Next comes a small heating chamber C placed alongside the float chamber and connected thereto in such a way that the level of the fuel is the same in the two chambers. In this heating chamber is a coil of wire connected with the battery which heats up the fuel in the chamber. The air is admitted through pipe D, located, as shown, partly in the exhaust pipe. The hot air from D enters the induction pipe at right angles to the fuel rising from the jet. Hence there is admission of actual exhaust gases and of very highly heated air into the induction pipe beyond the carburetor, in addition to the warm air which normally enters the car-

(... *The Engineer*, vol. 126, no. 3272, September 13, 1918, pp. 227-228, 2 figs., *d*)

Power Plants

BY-PRODUCT INSTALLATION FOR POWER STATIONS, Klingenberg. (*Zeits. Vereines Deutsch. Ing.* 62, p. 1, Jan. 5, 1918. *Elek. Zeits.* 39, pp. 176-177, May 2, 1918). The author first reviews the trend of the market for by-products. A great increase in production will cause a fall in prices and, in particular, the price of ammonium sulphate is likely to decrease owing to competition between the numerous nitrogen plants erected during the war, including those working the Haber process.

He then reviews distillation processes (coking and gas making), and deals with the erection and operation of plants for gasifying the whole of the fuel and recovering by-products. A gas of high calorific value at low temperature is required, and low temperature is needed in the producer if the tar and ammonia compounds are not to be dissociated. One of the most serious obstacles to the design of a large, high-efficiency installation is the limit of 650 to 1030 kw. obtainable from one producer unit, compared with 3000 to 5000 kw. from a steam boiler. The need of auxiliary steam supply is an important factor in the heat balance.

The author investigates in detail the relative economy of three types of power-station plant: namely, steam turbines with coal-fired boilers; steam turbines with gas-fired boilers and by-product plant; gas engines with by-product plant. In order to cover uncertainties regarding yield and price of by-products, three cases are assumed: (1) 6.44 M. per ton of coal; low yield and low prices; (2) 12 M. per ton of coal; good yield and good prices; (3) 17.56 M. per ton of coal; good yield and very high prices. Other assumptions made are: 1 to 1.5 per cent nitrogen content of coal; 68 per cent thereof recovered; 12 per cent light-load consumption of producer; 70 per cent full-load efficiency; 50 kg. tar per ton of coal; 2.2 kg. auxiliary steam per ton of coal, 0.8 kg. being raised by producer heat, 1 kg. by exhaust heat in the case of gas engines, and the rest by special boiler. The peak load of the station is assumed to be 100,000 kw., the size of the turbine units 20,800 kw. and of gas engines 6100 kw. each. The latter is relatively a higher limit than the assumed size of the turbine units, yet it involves 22 gas engines as compared with 6 turbines. The heat consumption on full load is taken to be 4360 kg-cal. per kw-hr. for steam turbines, 3570 kg-cal. for gas engines; and 13 per cent and 45 per cent of these figures on light load.

Objections to gas engines are: High total first cost; influence of gas composition; expensive attendance; repair and lubrication; vibration of foundations; small overhead capacity. Variable load involves increased heat loss and less satisfactory yield of same kw-hr. output in each case. The coal consumption of a steam-turbine plant with coal-fired boilers is exceeded in by-product plant with gas-fired boilers by 150 per cent, and with gas engines by 40 per cent. According to this, it is better to burn considerably less coal without by-product recovery than to burn much more coal in recovery plant. At least, no generalization is possible, and the economic justification for by-product recovery must be established in each particular case.

The capital costs for the three types of plant are estimated to be: Steam turbines without by-product recovery, 22.5 million M.; steam turbines with by-product recovery, 46.2 million M.; gas engines with by-product recovery, 47.6 million M. The capital burden is heavy in cases (2) and (3), but the price of coal is a more important factor with by-product recovery than without it. When the price of by-products is low, gas engines are at a disadvantage compared with steam plant, and the lower the revenue from by-products the greater the justification for direct combustion.

The author concludes that few by-product installations are economically justifiable where German hard coal (low in nitrogen) is employed. Even with medium nitrogen content it is unprofitable unless the price of tar and sulphate is well maintained. Steam turbines with by-product recovery are at an advantage compared with gas engines if the price of coal be less than 14 M. per ton. At higher coal prices, and with a by-product revenue of 10 M. per ton of coal, the field of competition of the gas engine is entered, but even then it is necessary to assume a higher load factor than can generally be realized in practice. If the by-product revenue be only 12 M. per ton, the load factor should be 60 per cent; and if the load factor be only 40 per cent, the by-product revenue should be 18 M. per ton of coal. Artificial improvement of load factor by chemical or metallurgical loads is not to be recommended if the latter could otherwise be served by water power. Direct combustion of coal is advised under any operating conditions if the revenue from by-products is less than 8 M. per ton of coal. The gasification of brown coal offers rather better possibilities than hard coal, particularly as regards the possible recovery of tar, fuel oils, and lubricating oil, but the gross saving anticipated from a quite favorable combination of circumstances does not appear to justify the commitments

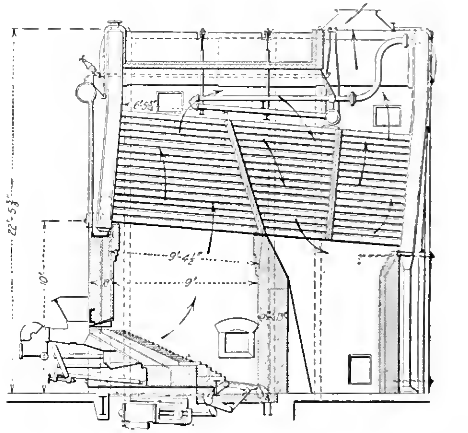

FIG. 6 SETTING FOR UNDERFEED STOKER, CEDAR RAPIDS PLANT

involved. Neither the amount of coal which could reasonably be subjected to by-product recovery, nor the revenue to be expected from such recovery, is as great as many writers have assumed. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, pt. 8, no. 248, August 31, 1918, pp. 281-283, *g*)

CEDAR RAPIDS BIG STEAM PLANT. Description of a 16,000-kw.-turbine plant giving commercial and railway service, and which in addition is selling steam for heating and also supplying large quantities of live steam for cooking. The amounts of heating steam are quite large and, for example, last January 70,000,000 lb. of steam were delivered to the heating system and the same amount of make-up had to be heated from an average temperature of 40 deg. to 210 deg. without the assistance of an economizer.

The use of so much raw water with its consequent deposits of scale and fouling of boiler tubes is one of the disadvantages under which the plant has to operate. The conditions under which the plant operates are, however, so variable that water softening is unadvisable. This variability of operating conditions makes it necessary to provide stokers which will respond to quick changes in load and will operate at considerable overload with Iowa coal. Underfeed stokers are used and the setting is as shown in Fig. 6. There the stoker is set flush with the boiler front, and with straight walls front and rear the combustion space is as large as the headroom of 10 ft. will permit, the volume approximating 880 cu. ft.

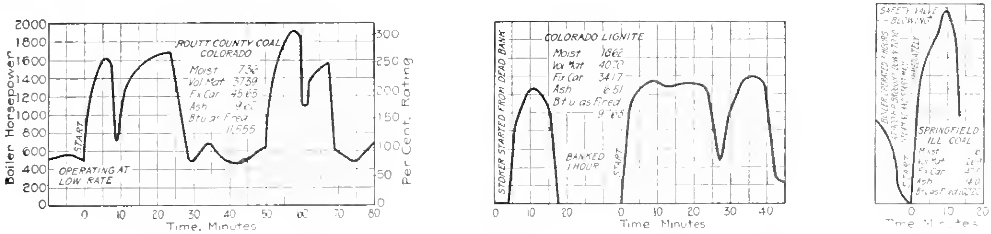

Fig. 7 Flexibility-Test Curves with Stokers on Low-Grade Fuels at Cedar Rapids Plant

Seven-retort stokers serve water-tube boilers rated at 627 hp. Operating at boiler rating, each stoker burns from 2500 to 3000 lb. of coal per hour and upon an occasion as high as 7400 lb. of coal per hour were burned, or over 1000 lb. per retort.

The three curves of Fig. 7 indicate the flexibility of operation. In the test with Colorado lignite (central figure) the stoker was started from a "dead bank." A high output was required for a short interval and then the load was taken off completely. The stoker is banked for an hour and is then called to meet a sudden and long-continued demand. The figure on the right shows a quick building up with the safety valve blowing at the top of the curve. These curves show that the stokers even when burning inferior coal will care for quick changes in load and will maintain heavy overloads at high efficiency.

In this instance the stoker engines are independent of the fan engines. The former are installed on the boiler-room floor with chain connections to lineshafts in the basement and driving chains from shaft to stoker. One engine will serve two boilers.

The electrical part of the plant is somewhat unusual in that the generation is all two-phase 2300-volt and the distribution three-phase with the exception of feeders for city service. The original article gives a single-line diagram for the two-phase, three-phase differential relays. The out-of-town service is three-phase 33,000 volts, the current being stepped up by two sets of 600-kw. two-phase three-phase transformers connected in multiple between the 2300-volt and the 33,000-volt buses.

All the high-tension lines are controlled from the operator's room equipped with means for remote control of the oil switches, as well as telephone connections to the city system and by a private line to the various stations operated by the company as well as the boiler and turbine rooms. (*Power*, vol. 48, no. 14, October 1, 1918, pp. 478-485, 12 figs. and list of principal equipment, *dA*)

New Plant of the Pennsylvania Salt Manufacturing Company. The plant is located at Wyandotte, Mich., 12 miles from Detroit, and the addition described in the present article was laid out specifically for convenience of operation, with plenty of room to make repairs to allow for future extension without disarranging the present layout.

The boiler room has been made the prime factor of the plant, and has an equipment consisting of modern types of water-tube boilers, underfeed stokers and economizers.

An interesting feature of the plant is the centering of the control of all boiler-room auxiliaries in an operating board, on which are also grouped a variety of instruments (indicating and recording) giving all information necessary for the efficient operation of the plant.

In the main feed line to the boilers there is a venturi tube with a manometer, and also a thermometer to measure the feedwater, the instruments being located on the operating board. On the board there is also a steam-flow meter for each boiler. The latter instruments show the output in each case, and the aggregate readings may be checked against the total input shown by the water meter in the supply line.

The control of the dampers is also centered on the operating board. In this board there are six panels, one for each boiler. These panels contain the handwheels to the dampers in the breeching and in the forced-draft inlets, a steam-flow meter and draft gages showing the draft over the fire and in the last pass of the boiler, and the pressure under the stokers. One panel contains, in addition to the flow meter on the feedwater referred to above, a pyrometer and multiple switch, draft gages showing the draft on the stack side of the economizers and the handwheels for controlling the vertical dampers at the economizer outlets. The last panel has two large dial gages showing the pressures at the turbine throttles, in addition to which there are the three field rheostats and ammeters for the forced-draft fans and the stoker motors.

At the side of the operating board there is a recording-gage panel containing four pressure-recording gages, two of which give the pressure at the turbine throttles and the other two record the pressure on the feedwater system, one before the economizers and the other at the delivery to the boilers.

One recording thermometer charts the temperature of the water entering the boilers and another the temperature of the water entering the economizers, in addition to which each battery is served by a CO_2 recorder.

The above constitutes an unusually complete set of apparatus and affords a good basis toward efficient operation of the plant.

Another feature of interest in the plant is the use of three eductor-type jet condensers (Fig. 8) taking the exhaust steam from the auxiliaries and the condensate from the main condensers. The latter at a temperature approximating 90 deg. is forced through the jet condensers, where its temperature is raised by the auxiliary exhaust to about 150 deg., which is considered to be the most economical temperature for the economizer.

The condensers are connected in parallel, and any number of them may be operated at one time, or the condensate may be bypassed directly to the hotwell. (*Power*, vol. 48, no. 12, September 17, 1918, pp. 406-413, 10 figs., *da*)

Railroad Engineering

RENEWABLE STAY HEADS FOR LOCOMOTIVE FIREBOXES. Data of experiments by Mr. Snelson, Chief Foreman Boilermaker, in the Locomotive Works at Crewe, England. This led to the development of a new method of repairing locomotive firebox stays recently adopted on the London and Northwestern Railway Company's lines.

Fig. 9 gives a plan and elevation of one of these heads for insertion, and also shows the head in position. It is to be used chiefly for renewing small or defective stay heads. The small and defective stay head is hammered up in order completely to expand it in the hole. It is then centered, drilled and tapped to a depth of about $\frac{5}{8}$ in. for the front side of the plate. The stay end and firebox plate are then lightly skimmed up with the facing cutter. This facing cutter, which is equal in diameter to the new head, is screwed into the tapped hole to insure obtaining a face that is perfectly true with the hole. By this operation the stay is made ready for the new head. A thin copper washer is then inserted between the face of the new head and the copper stay, and the head is tightly screwed in by means of a wrench on the square end.

The heads have been tested in several instances, described in the original article and showed up quite well. Among other things, there was some uncertainty to whether the repaired stay would be strong enough to withstand the various stresses set up in the firebox. Fracture tests were, therefore, carried out in the testing department at Crewe, and it was found that even on the smaller stays there is a good factor of safety. Thus, a 1-in. stay fitted with the head of the new type in a boiler working at 150 lb. pressure per sq. in. has a factor of safety between 6.5 and 7 when the stays are pitched 4 in. apart, while on stays $1\frac{3}{16}$ in. and $1\frac{1}{4}$ in. in diameter and upward, the net section of the repaired stay is greater, and consequently stronger than the original 1-in. or $1\frac{1}{16}$-in. stay.

Various instances are cited in the original article to show

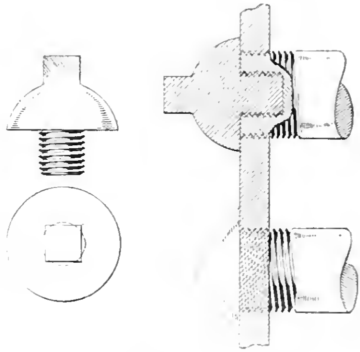

FIG. 9 SNELSON RENEWABLE STAY HEAD FOR LOCOMOTIVE FIREBOX

the durability of the new type of head. Thus in one case 21 of these heads were put in the firebox sides of a loco-stationary boiler in December 1916. Since then it has been worked continuously night and day, week ends and holidays excepted, and up to the present time not one head has given the slightest trouble. Early in October 1917 this boiler was stopped for cleaning, and advantage was taken of this stoppage to take one of the heads out for inspection purposes. It was found that in outline the form of the head was practically unchanged, even the square portion being in such good condition that it was used to withdraw the head, as it was used 10 months before to insert it.

The copper liner that had been threaded on the head was intact and the copper plate underneath the head was in splendid condition. (*The Engineer*, vol. 126, no. 3270, August 30, 1918, pp. 176-177, 5 figs., *d*)

Refrigeration

THROTTLING OF AMMONIA, Chas. D. Herter. From time to time the question has been raised whether during a shortage of ammonia any disadvantage might result if, instead of regulating several expansion valves singly, the main liquid valve (also known as the king valve) at the liquid receiver was throttled down so as to obtain at once the desired reduced feed in liquid to the refrigerating coils.

The writer comes to the conclusion that intermediate throttling of liquid is entirely proper under certain conditions, the only possible harm being more rapid wear of the valves used. From a thermodynamic viewpoint no noticeable benefit is obtained by reducing the pressure upon the liquid gradually instead of all at once, while the provision of an emergency feed valve, in addition to the main liquid valve ordinarily left fully open, is considered good practice. (*Power*, vol. 48, no. 15, October 8, 1918, pp. 530-531, *p*)

Steam Engineering

Pumping Engines for the Cairo Main Drainage. Description of the engines used in the new main drainage system of the City of Cairo, in Egypt. This machinery consists briefly of four sets of pumping engines each driving direct from the engine crossheads a set of triplex single-acting plunger pumps.

The pumping engines themselves may be described as being of the inverted vertical quadruple-expansion three-crank type having the high and first intermediate cylinders placed tandem over the center crank and the second intermediate and low-pressure cylinders placed one on either side of the first intermediate cylinder and over the outer cranks.

The chief point of interest lies in the arrangement of the high and first intermediate cylinders, which, as shown in Fig. 10, are single-acting. In fact, the arrangement is equivalent to one double-acting cylinder as far as the number of valves and amount of valve gear are concerned, with the advantage of a reduced temperature range with each cylinder.

The pistons of the two cylinders are in one piece forming what may be called a differential piston. The upper part of this piston is in plunger form and fills the high-pressure cylinder for the whole length of the stroke, thus preventing the cooling of the high-pressure cylinder walls by contact with the lower-temperature steam content in the annular space in the upper part of the first intermediate cylinder. The following advantages are claimed for such an arrangement as compared with the more usual plan of providing two superimposed double-acting cylinders: In the first place, there is a material reduction in the number of valves and their consequent working parts with a corresponding reduction in steam leakage. There is also a reduction in the overall height of the engine and, in addition, a simple and secure base is obtained for the high-pressure cylinder. Further, the gland and stuffing box on the high-pressure cylinder, which the usual double-acting construction would require, and which would tend to be a source of trouble, are eliminated.

The steam cylinders are, respectively, 17 in., 27 in., 33 in. and 49 in. in diameter with a common stroke of 36 in., and when running at normal speed of 22 r.p.m. each engine is capable of developing 200 hp.

All of the valves are actuated by a lay shaft carried along the front of the cylinders and rotated at the same speed as the crankshaft with skew gearing on a vertical shaft reaching from the crankshaft to the valve-motion lay shaft. By the use of this lay shaft heavy eccentrics, rods, and rocking levers are dispensed with. The steam valves of all cylinders are fitted with the trip motion giving practically instantaneous closing the shock of the drop valves being absorbed by oil-cataract dashpots to insure silent working, while the Corliss valves are controlled by spring dashpots of the usual type. The exhaust valves are controlled throughout by positive-motion gear.

Owing to the type of link mechanism adopted for actuating the valves, the distortion due to obliquity of the usual eccentric gear is practically non-existent; this was found to be a distinct advantage in adjusting the valve motion relatively to the actual working steam pressures, in view of the somewhat unusual differences in pressure between the upper and lower ends of the two final cylinders, due to the fact of the first two cylinders being single-acting. In order to equalize the pressures, and avoid the loss due to "drop" between succeeding cylinders, reheater receivers of ample proportion are provided. These are fitted with solid-drawn steel tubes, and are coupled to the jacket system, so that steam at initial pressure and temperature is continually circulated through the tubes, thereby drying and reheating the working steam on its passage to the succeeding cylinder. (*Engineering*, vol. 106, no. 2749, September 6, 1918, pp. 251-252 and one plate of drawings, *d*)

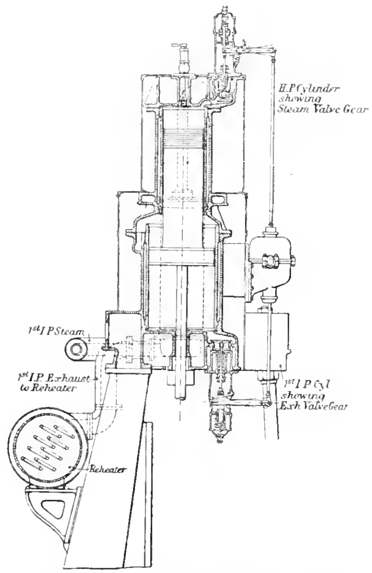

Fig. 10 High and First Intermediate Cylinders of the Pumping Engines for the Cairo Main Drainage

A New Theory of the Steam Turbine, Harold Medway Martin. Continuation of abstract of a serial article. Previous installments of the abstract appeared in The Journal, September 1918, page 784, and October, page 871.

In the previous article it was shown that adiabatic heat drop cannot under all conditions be taken as proportional to the actual effective thermodynamic head and that where the superheat is high the reheat factor is also high and vice versa.

In the present article the author shows how to determine the point at which different degrees of initial superheat are lost.

Assume for example that the initial pressure is 180 lb. absolute and that the hydraulic efficiency of the turbine is 70 per cent. Suppose the superheat to be lost at, say, 80 deg. cent. The volume of the steam is then 54.596 cu. ft. per lb. (Callendar) and its pressure is 6.8627 lb. per sq. in.

The initial pressure being 180 lb. absolute, we have

$$x = \frac{p_1}{p_2} = \frac{180}{6.8627}$$

If ρ be the ratio of the final volume to the initial volume then, since the expansion follows the law $pV^m =$ constant (where $m = \lambda$), we have $\rho = x^{1/m}$

The value of $1/m$ is given (p. 53 ante) by the relation

$$\frac{1}{\lambda} = 1 - 0.23077\,\eta = 1 - 0.23077 \times 0.7 = 0.8385$$

Whence

$$\rho = \left[\frac{180}{6.8627}\right]^{0.8385} \quad \text{and} \quad V_1 = \frac{V_2}{\rho} = 3.528 \text{ cu. ft. per lb}$$

Reference to Callendar's table shows that steam at 180 lb. absolute with this specific volume has a temperature of 331.6 deg. cent., corresponding to a superheat of 142.1 deg. cent. or 255.8 deg. fahr. By determining a number of values in this way and plotting the results as curves, the temperature at which any stated initial superheat is lost can be determined. The writer gives a table showing the appro imate temperatures in centigrade at which superheat is lost for different hydraulic efficiencies when the initial pressure is 180 lb. absolute. With the temperatures given in such a table it is possible to calculate the total effective thermodynamic head, or, to

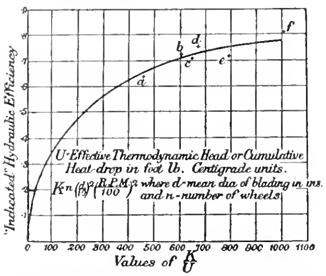

FIG. 11 "INDICATED" HYDRAULIC EFFICIENCY OF IMPULSE TURBINES IF STEAM EXPANDS IN THERMAL EQUILIBRIUM THROUGHOUT

use Professor Goudie's terms, the cumulative heat which becomes available in a turbine when expanding steam from 180 lb. absolute to 1 lb. absolute with different hydraulic efficiencies, the steam being supposed to be in thermal equilibrium throughout. The author gives a table of cumulative available heats when steam expands in thermal equilibrium from an initial absolute pressure of 180 lb. per sq. in. to 1 lb. absolute with different hydraulic efficiencies and different initial superheats. This table

TABLE 1 CUMULATIVE AVAILABLE HEATS F. P. C. WHEN STEAM EXPANDS IN THERMAL EQUILIBRIUM FROM AN INITIAL ABSOLUTE PRESSURE OF 180 LB. PER SQ. IN. TO 1 LB. ABSOLUTE; WITH DIFFERENT HYDRAULIC EFFICIENCIES AND DIFFERENT INITIAL SUPERHEATS

Hydraulic Efficiency η	Initial Superheats, Deg. Fahr.						
	0	50	100	150	200	250	300
0.5	201.3	207.2	216.2	226.9	238.9	251.1	262.4
0.6	197.4	203.5	210.3	219.4	229.6	240.4	251.4
0.7	191.1	199.2	206.7	214.2	222.6	232.9	241.3
0.8	190.7	196.3	202.5	209.3	216.9	228.5	233.6
1.0	181.1	189.5	195.4	201.7	208.2	215.0	222.0

is here reproduced as Table 1. To determine from this table the theoretical steam rate for a turbine working with different superheats a correction is required because increases in the effective thermodynamic head change the ratio of blade speed to steam speed.

This correction can be effected by means of the curve plotted in Fig. 11 on the assumption that thermal equilibrium was maintained throughout the whole expansion. In this curve the "indicated" hydraulic efficiency of a number of impulse turbines is plotted against K/U, where

$$K = n\left(\frac{d}{10}\right)^2\left(\frac{\text{R.P.M.}}{100}\right)^2$$

and U denotes Ru, where u is the adiabatic heat drop. In the above expression for K, the number of stages is represented by n, while d denotes the mean diameter of the blading. Since the average velocity of the steam is proportional to $\sqrt{(U/n)}$, the expression $\sqrt{(K/U)}$ is proportional to the ratio of blade speed to steam speed. According to the ordinary view the indicated hydraulic efficiency should give a parabola when plotted against $\sqrt{(K/U)}$, and consequently the curve in Fig. 11 should be an ellipse. The points lie badly on an ellipse, however, and the curve shown has been sketched in freehand. As will be shown later, a much better agreement between the curve and the experimental figures is obtained when the theory that the steam expands in thermal equilibrium is abandoned. (*Engineering*, vol. 106, no. 2744, August 2, 1918, pp. 107-108, abstract to be continued, *tA*)

GRAPHIC METHOD OF DETERMINING SIZE OF SAFETY VALVES, H. F. Jauss. The writer gives a simple method of determining the proper size of safety valve for a steam boiler. This method is based on the rules set forth in the A.S.M.E. Boiler Code, with a modification in the ma imum allowable lifts, which have been increased 25 per cent above those given in the Code. The reasons for this increase are: (1) That it is possible to manufacture successfully safety-valve springs capable of these

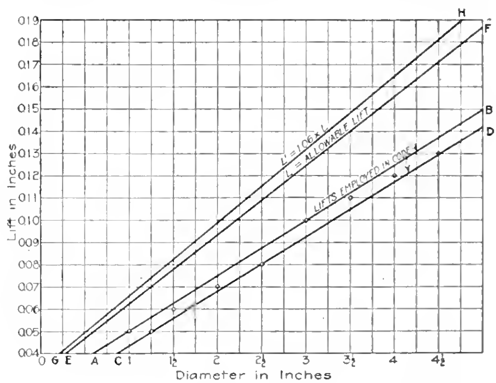

FIG. 12 RELATION OF LIFT OF VALVE TO DIAMETER

higher lifts; (2) that this decreases the number and size of valves required; (3) that the large margin of safety secured by restricting the maximum lifts to very low values as in the A.S.M.E. Code is not necessary, since at best the safety valve can only take care of a gradual increase in pressure and does not protect against a sudden increase.

The writer derives the chart in Fig. 12, where the lines *AB* and *CD* indicate the limits of the maximum lifts employed in constructing the safety-valve tables in the A.S.M.E. Boiler Code where the constant lift is employed for each size of valve regardless of the pressure. Assuming that lifts 25 per cent greater than the A.S.M.E. maximum are possible, it is easy to determine a new line *EF* indicating the maximum possible lifts for valves of various diameters.

For the construction of capacity curves, the writer uses the modified Napier's formula and also gives an alignment chart for finding the size of safety valves. A numerical example is given and fully worked out. (*Power*, vol. 48, no. 12, September 17, 1918, pp. 414-417. 3 figs., *g*)

Tests on Steam-Engine Governing, Prof. Anton Gramberg. The following tests were carried out for the purpose of elucidating the phenomena occurring when engines are automatically governed. They were carried out with a horizontal steam engine working non-condensing. The engine was equipped on the high-pressure cylinder with the so-called old Collmann valve gear regulated by a governor in the usual manner, the governor being driven as shown in Fig. 13. The position of the sleeve can be read at *r*.

The weight of the governor was 108 kg. The additional weights shown in Fig. 13 are not included in this weight.

As a rule, during the tests the governor was equipped only with the running weights displaced horizontally by hand, and so arranged as to change the speed of the engine roughly from 120 to 135 r.p.m.

In addition to this, for the purpose of experiment, there was added to the governor shaft a spindle on which the weights I and II could be located at definite intervals above and below the governor shaft. When this spindle is exactly vertical these weights exercise no effort either on the governor shaft or on the governor itself, and the spindle is in such a vertical position when the governor sleeve and the governor shaft are in exactly central position; but if the governor shaft moves out, these additional weights very rapidly create increasing moments on the governor shaft and, hence, with equal rapidity, increasing forces on the governor sleeve. These forces pass from negative values through zero to positive values (counting them algebraically in the same sense all the time) and their increase is approximately proportional to the paths traveled by the governor sleeve, the speed of the rise being approximately proportional to the distance either above or below the weights from the governor shaft.

One can investigate the action of these variable weights (which can be displaced either in the horizontal or in the vertical direction) on the governing by varying the electrical load N_{el} on the machine, so that the governor will assume various positions for *r* and then by observing the corresponding speeds *n*.

In these tests the horizontal weight was displaced first. It weighed 18.15 kg. (40 lb.) and was displaced from its normal position to the left to a distance of 0.1 m. (3.94 in.) and then shifted through a distance of 0.2 m. (7.87 in.) entirely to the right. The arm of the governor shaft, on which the force acting on the sleeve was applied was 0.141 m. (5.56 in.), therefore the displacement of the weight exerted additional forces on the sleeve equal to $18.15 \times \dfrac{0.1}{0.141} = 12.9$ kg. (28.4 lb.) or $18.15 \times \dfrac{0.2}{0.141} = 25.8$ kg. (56.8 lb.), respectively. When the output of the engine was made to vary, the readings were such as shown in Fig. 14. For the two end positions and the middle position of the governor weights there were obtained the three rising characteristic curves of governing parallel to each other.

It appears, therefore, that the horizontal displacement of the weights caused the characteristic curve of governing to shift to the right, but did not produce its turning. It affects the speed of rotation but not the degree of lack of uniformity of governing.

The behavior of the curves of equal output N_{el} (Fig. 14) of the steam-engine generator set is also of interest. At higher speeds a smaller torque corresponds to the increased output, and therefore one would expect a higher position of the governor. This is what actually occurs at all loads, but not when the set is running idle. In this latter case the internal resistances of the set determine what happens, and these play only a very minor rôle at higher loads. Now, the moment of the internal resistances increases with the speed of rotation, and therefore when the set is running idle the governor goes

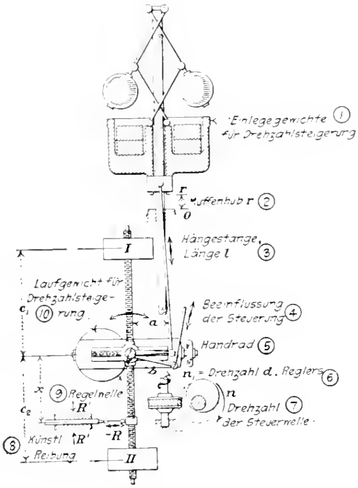

Fig. 13 Diagrammatic Sketch of the Experimental Governor Installation

(1) Additional weights for raising the speed of rotation of the governor; (2) Sleeve travel *r*; (3) Connecting rod, length *l*; (4) Valve-gear control; (5) Handwheel; (6) n_1 = r.p.m. of governor; (7) *n* = r.p.m. of the layshaft; (8) Artificial friction; (9) Governor shaft; (10) Weights for varying the speed of rotation of the governor.

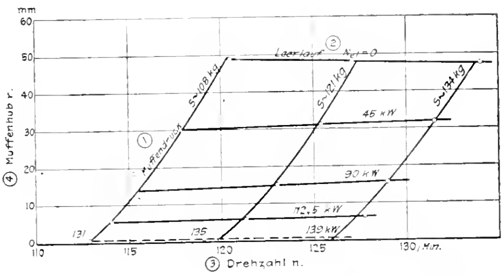

Fig. 14 Characteristic Curves of Engine Governing at Variable Speeds

(1) Sleeve pressure; (2) No-load operation; (3) Speed of rotation, *n* r.p.m.; (4) Sleeve travel.

down with the increase of speed; more steam when the set is running idle means a higher rate of speed on the engine.

If the weights be shifted in the vertical direction, the curves obtained will be those shown in Fig. 15. In that case the governor was first in its usual position. Next, the weight of 20 kg. (44.0 lb.) was placed 0.3 m. (11.8 in.) below the governor shaft, this corresponding to an addition of a product of forces × arm (this latter considered as being horizontal) = —6 m-kg. In the three instances the weight of 10 kg. (22.0 lb.) was lo-

cated 0.3 m. (11.8 in.) above the governor shaft, giving an additional moment of + 3 m-kg.

Under the influence of these additional weights the characteristic curves of governing undergo a rotation without displacement. They become steeper when the weight is located above the axis of governing and the governing itself tends to become astatic. On the contrary, when the weight is located under the governor axis, the characteristic curve becomes flatter and the regulation assumes a strongly static condition. The average speed of rotation of the engine is maintained, but the degree of lack of uniformity varies. When the weight is located below the axis it tends to pull the governor into its middle position, which makes greater variations in speed necessary in order to permit it to resume its end position. On the contrary, weights located above the governor axis push the

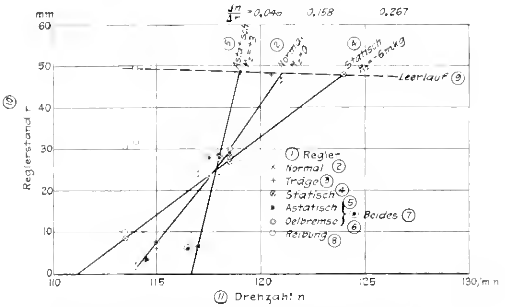

FIG. 15 CHARACTERISTIC CURVES OF ENGINE GOVERNING AT VARIABLE STATIC CONDITIONS AND VARIABLE STEAM DELIVERIES

(1) Governor; (2) Normal; (3) Sluggish; (4) Static; (5) Astatic; (6) Oil brake; (7) Both; (8) Friction; (9) No-load operation; (10) Position of governor r; (11) Speed of rotation, n r.p.m.

governor into its end position, so that only slighter variations of the speed of rotation become necessary.

In connection with Fig. 15, if weights of 10 kg. (22.04 lb.) be located 0.32 m. (12.59 in.) both below and above the governor shaft, neither the speed of rotation nor the degree of lack of uniformity of the governing will be affected. The mass of the governor is increased and the governor itself made more sluggish. The points "sluggish" and "normal" lie close to each other in Fig. 15, although the mass of the governor is increased by $20 \times (0.32\ 0.141)^2 = 103$ kg., which is considerable in comparison with the original governor mass of 130 deg. But the mass as such (that is, when it is equalized and does not come into action as a weight) has no influence on the static behavior of the governing.

Fig. 15 presents data of a further series of tests in which the motion of the governor was first subjected to damping artificially and next to molecular damping. The method by which mechanical damping was produced is shown in Fig. 13. As shown in the lower left corner of that figure, two cheeks are rubbing with a force R' (which can be adjustably varied) against a central piece drawn back and forth between the cheeks by the motion of the governor. Molecular damping is produced by an oil brake displacing this frictional damping. Fundamentally, the two arrangements are different in that in the case of an oil brake the damping force increases (by a law approaching the square law) as the velocity, and, what is more important, it converges toward zero along with the velocity. In the case of the mechanical damping device the damping force is practically independent of the velocity and is equally large when at rest. This, however, is not new.

Hence, in Fig. 15 the points, even with the oil brake in operation, lie in a regular manner, while the point of rest is not affected by the oil brake. On the other hand, the frictional damping produces a broad scattering of the point of rest of the governing and thus shows permanent irregularities.

All the above had a bearing on the question of the manner in which the speed of rotation n and the governor position r came to a permanent state under the influence of the governing properties of the governor. From this the author proceeds to an investigation of the manner in which the governor effects a passage from one position to another. This part of the article is quite extensive, illustrated by numerous curves, and is not suitable for abstracting. (*Versuche an einer Dampfmaschinenregelung*, Prof. Anton Gramberg, *Dinglers Polytechnisches Journal*, vol. 333, no. 4, February 23, 1918, pp. 25-30, 6 figs. *e*)

Testing

TESTING THE RELATIVE MERITS OF CASE-HARDENING MATERIALS, Chas. N. Underwood, Mem.Am.Soc.M.E. Case hardening may be said to consist of two parts: the first, carburizing the steel shell about the low-carbon soft steel; and the second, hardening this carburized shell by quenching when at a high heat. The second element is easily controlled and the problem is therefore only to find a case-hardening material best apt to give up its carbon to the steel. A test of such a material resolves, therefore, into finding a material which will give the deepest, densest and most uniform case under constant conditions of time, temperature, packing and quenching.

The present article describes the method of testing employed by the Remington Typewriter Works. The test pieces, 3½ in. long and 1 1/16 in. in diameter, were cut from a bar of round, bright machine-screw steel and packed in boxes, two pieces in each box. The box was completely filled with the case-

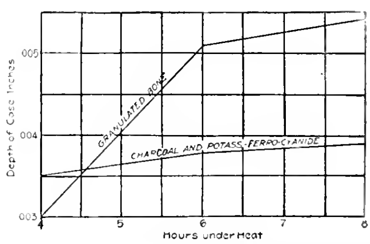

FIG. 16 RESULTS OF TESTS ON CASE-HARDENING MATERIALS

hardening material and the cover sealed with fireclay. Three boxes were packed with each kind of material, the materials tested being charcoal and potassium ferrocyanide, and granulated bone.

Special attention was paid to the proper location of the boxes in the furnace. The boxes were placed in rows and one row was removed from the furnace after four hours, one row after six hours, and one row after eight hours. As each box was removed the test pieces were taken out and quenched in cold water and the test numbers checked to insure the accuracy of the record. A log of the furnace temperatures was kept throughout the test. From this log it appears that after the specimens were placed in the furnace the temperature was raised until it reached 1800 deg. fahr. about one hour later.

The temperature was then cut down to, and held at, approximately, 1600 deg. fahr.

After hardening the test pieces were taken to the grinding

room and a groove was ground through the case completely around the circumference at about the center of the piece. The pieces were then sawed into two parts at the groove and the cut end of one of the pieces ground flat, highly polished with very fine emery and etched with a 20 per cent solution of nitric acid. Two lines perpendicular to one another were then scribed on this polished surface by means of a fine needle set in a steel holder, the depth of these lines, to a certain extent, indicating the hardness of the case. The original article describes, in some detail, the method of measuring the depth of case.

Fig. 16 gives the plotted results of measurements with the two case-hardening materials, which indicate that for a four-hour run the charcoal mixture gave a deeper case, but for longer runs granulated bone appeared to be more efficient. With both materials, however, the depth of case increased steadily up to a period of six hours, further increase of depth being at a much slower rate. (*American Machinist*, vol. 49, no. 13, September 26, 1918, pp. 569-571, 3 figs., *ep*)

Telescopic Focusing Apparatus for Photomicrography, A. F. Hallimond. There are certain difficulties in using an ordinary vertical camera in connection with the microscope. When the plate is supported at a distance of 10 in. or more above the microscope the height of the focusing screen often becomes the source of much inconvenience. Oscillation of the camera at opening of the dark slide is also troublesome.

To obviate these difficulties the telescopic arrangement described and illustrated in the present paper was designed. It resembles the ordinary form of reflex focusing camera. The rays proceeding from the microscope eyepiece which would normally converge to a focus on the photographic plate are reflected horizontally by a movable mirror. This mirror is attached to a metal plate large enough to cut off all light from the camera when in proper position and is held there by an adjustable stop. The deflected beam is focused by the telescope objective with the focal length of 4 in. upon cross-wires and the image so formed is seen together with the cross-wires when examined through the eye lens having a focal length of ¾ in.

To each length of camera there corresponds a fixed position of the focus to which the cross-wires must be set, but after this graduation has once been made it is sufficient in taking a photograph to fix the telescope for the proper camera length and focus the microscope so that the image is clearly defined on the cross-wires. The apparatus appears to be quite simple. (Paper before the September Meeting of the *Iron and Steel Institute,* abstracted through advance copy, 3 pp. 1 fig., *d*)

Ship Strain Recorder. A new device to record the "give" of a ship has been developed by F. R. McMillan, research engineer of the Concrete Ship Section, and H. S. Loeffler, assistant research engineer of the Section.

When equipped with this device, every strain that a ship experiences in a storm or, for that matter, in any weather, is recorded by little zigzag waves on a strip of paper which passes under a recording needle in the instrument. The apparatus was tried out on the concrete steamer *Faith* on her first voyage.

The "Strainagraph" is built somewhat on the principle of the seismograph. It may be destined to play an important part in future ship designing, for it gives a simple medium for comparison of the relative strength of different types of ships. Numbers of these instruments, placed in different parts of the ship, would show any weaknesses and give the expert a workable chart upon which to build an analysis or "diagnosis" of a ship's seaworthiness.

Primarily the instrument was designed to test out the qualities of the concrete ship just now passing from the experimental stage.

The strainagraph is attached at any point in a ship where it is desired to know the strain. A series of levers which multiply 140 times any movement transmitted to them is actuated by a plunger bar fixed to the ship at a point 40 in. distant. Thus the distance recorded on the chart is 5600 times the actual movement in any one inch of length.

The chart showing the record has a line at the top with breaks at intervals. Attached to the instrument is a clock which serves to measure on the chart the time during which the record is produced. Every double break in the top line marks the end of a minute and every single break the passing of a quarter of a minute.

The recording pen which records the zigzag line in the center of the chart travels upward when recording compression and downward when recording extension.

The instrument on the *Faith* was located amidships on a longitudinal deck beam about midway between hatches 2 and 3 on a line along the port side of these hatchways. (*Emergency Fleet News*, October 3, 1918, p. 13)

Varia

Mast Turning Lathe. The Traylor Shipbuilding Corporation, Cornwells Heights, Pa., has in operation in its yard a mast turning lathe that is one of the new developments in shipbuilding since the Emergency Fleet Corporation was created. Formerly the making of masts was a long and laborious operation fit for the best work of especially skilled men. The machine will handle timbers for a mast up to 100 ft. long and 3 ft. in diameter. The timber, after being centered and set up in the machine, which usually requires about half a day, is revolved at a speed of 50 r.p.m., by means of an electric motor, thus coming in contact with the cutter head, which is mounted on a carriage attached to the motor, and set at right angles to the mast. The cutter head revolves at a speed of 700 r.p.m. In this head are three hooked knives, which cut the material from the mast.

The carriage is propelled by a wire rope on a gypsy head, which also is run by a motor, the feed of the carriage being practically the same as on an old-fashioned sawmill.

When a mast is extra long and sags in the middle, it is necessary to put a steady rest at the point where the sag is greatest, thereby making the timber run true. To get the shape of the mast, that is, the taper at the top, it is necessary to set a rail which is bolted down to the bed of the machine and bent in exact position as the profile of the mast which is to be cut. On this rail runs a shoe, controlling the cross-movement of the carriage. If the rail is set away from the machine, it pulls the carriage closer to the center of the mast. If it is set nearer it moves the carriage further away. (*Emergency Fleet News*, Oct. 3, 1918, p. 12, *d*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Ships for Foreign Trade

The Shipping Board is already taking cognizance of the opportunities and possibilities of trade development through the increase of the merchant marine of the United States. The following letter from Chairman Hurley of the Shipping Board has been sent to the Society:

To the Secretary:

The time has come for Americans everywhere to put themselves solidly behind American ships.

Our railroads must no longer stop at the ocean. We are building an American merchant fleet of twenty-five million tons—three thousand ships. We are backing modern ships with modern port facilities, establishing our bunkering stations all over the globe and will operate with American railroad efficiency. We will carry American cargoes at rates corresponding to our railroad rates—the cheapest in the world. Fast American passenger-and-cargo liners will run regularly to every port in Latin America, the Orient, Africa, Australia.

Are your members taking steps to use these ships to increase their own prosperity? Do they realize that American products of factory, farm and mine can be delivered to customers in foreign countries on terms which will build lasting trade? Do they realize the possibilities for bringing back raw materials to extend their products and trade?

We must all take off our coats and work to bring these American ships home to the people of every American interest and community. The manufacturer must think of customers in Latin America as being as accessible as those in the next state. The farmer must visualize ships carrying his wheat, cotton, breeding animals, dairy products and fruit to new world markets. The American boy must think of ships and foreign countries when he chooses a calling.

Has your organization appointed a live committee on Merchant Marine? Is the chairman of this committee a man of international vision? Are you applying the new world vision to the interests represented in your organization and learning what ships can do toward widening their markets?

Public neglect ruined our old mercantile marine. Congress was not to blame—it simply reflected the indifference toward ships of the average American. Once more we have a real American merchant fleet under way, backed by far-reaching policies for efficient operation. We must dispel indifference and keep our flag on the trade routes of the world. We are going to take trade from no other nation. But we must serve our own customers and help other nations in their ocean-transportation problems after the war.

Edward N. Hurley, *Chairman*,
United States Shipping Board.

Washington, D. C.

Recent Improvements in the Manufacture of 85 Per Cent Magnesia Insulation

To the Editor:

It has frequently been brought to the writer's attention that the results published in his paper entitled The Heat-Insulating Properties of Commercial Steam-Pipe Coverings are not fair to J-M 85 Per Cent Magnesia because of the fact that the samples tested were not representative of the J-M 85 Per Cent Magnesia manufactured at the time the paper was published and since that time.

The samples were taken from a stock where they had been stored for a considerable period, and in the interval between the time they were manufactured and the time the paper was published very important improvements had been made in the process of manufacturing. The writer has had excellent opportunities to observe the effect of this improvement in manufacture since he became associated with the H. W. Johns-Manville Company in the capacity of consulting engineer.

However, the new material was tested by the writer at the University of Wisconsin several months before he became connected with the H. W. Johns-Manville Company and the results given below are quoted from the report of that test. The test was made by identically the same methods and on the same apparatus as the test previously reported in the writer's paper. Furthermore, subsequent tests have checked very closely with the test of the new Magnesia here given, which fact shows that a uniformly better product has been developed.

"The test of J-M 85 Per Cent Magnesia, results of which are given in Trans.Am.Soc.M.E., Vol. 37, pp. 944, 946 and 958, was made in November 1914 and the sample was taken from the stock at the University Heating Station, where it had been on hand for some time, probably more than a year. Therefore, the new sample tested in February and March 1916 represented entirely a different product embodying the improvements in manufacture which had been made in the intervening period of two or more years.

"Description of samples:

	New	Old
Pipe size, in.	5.00	5.00
Weight per foot, lb.	2 73	2 92
Thickness, in.	1.11	1.08
Apparent thickness, in. (½ of outside diameter of covering—½ of outside diameter of pipe)	1.18	1.13

"Results of test:

DATE OF TEST: FEBRUARY 23 TO MARCH 2, 1916

Temperature Difference	B.t.u. per Sq. Ft. of Pipe Surface per Deg. Temp. Dif. per Hr.		Efficiency, Per Cent	
	New	Old	New	Old
50	0 373	0.435	80 9	77 7
100	0.381	0 438	82 3	79 6
200	0 397	0 446	85 1	83 3
300	0 413	0 455	87.3	86 1
400	0 429	0.469	89 4	88 4
500	0 445	0 488	91.4	90 6

"A comparison of the above figures shows the great superiority of the new Magnesia over the old."

L. B. McMillan.

New York, N. Y.

To Readers of The Journal

At the time these pages were approved for publication, there was a strike of press feeders in the printing establishments of New York City, including the one from which The Journal is issued. This will account for any delay experienced by readers in receiving the present number.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THE one great lesson of the war is the bringing home of the essential need of all to be mutually helpful—that we are interdependent—as individuals, as professions, as peoples.

It is not inconsistent with Washington's admonition against entangling alliances that this nation should develop "cultural relations" with other countries.

I was about to say neighbors, because we shall soon cease to regard any place as distant. Past-President Hartness told me the other day that shortly we would use the aeroplane as a developer of new sections in much the same manner as the railroad half a century ago, with the advantage that no highway is required.

Among the specific activities to which the Secretary wishes to attract attention is the American Engineering Standards Committee.

It is proposed to organize a committee representing the Government and the professional societies on much the same lines as the British Engineering Standards Association.

This association has for over fifteen years been doing consistent work representative of the whole British nation, whereas in the United States, however meritorious individual pieces of work, notably, specifications for materials, screw threads, boiler code and safety standards, nevertheless they have been haphazard and are representative only to the degree of care with which the individual sponsor society secured representative delegates to its conferences.

The International Electrotechnical Commission, the Pan-American Scientific Congress, the International Engineering Congress and the Aircraft Stadardization Board, in all but the first of which representatives of this Society have taken a conspicuous part, have led at least the English-speaking people to the necessity for Anglo-American Standards. The Secretary is in hope that international standardization will be contemporaneous with Anglo-American, but if that is an ideal not yet capable of attainment, let us by all means proceed with Anglo-American.

In another column is the letter from Mr. Hurley respecting our Merchant Marine. President Main would like all those in the Society who are interested to advise him and give their opinions as to how the Society may respond.

Intimately bound up with Mr. Hurley's invitation is the subject of development of relations with Central and South America. We have in the Monroe Doctrine the most emphatic basis for further intercourse. On the staff of the Society at headquarters we have, too, Mr. Leon Cammen, who speaks and reads sixteen languages, and Mr. Jesse E. Vera, who has traveled extensively in South America and speaks the languages fluently. The Secretary, therefore, is not only carrying out a lifelong activity but is confident he is doing that which the Society generally wishes to be done, namely, to encourage professional organizations throughout the world to send visitors to us and to promise every assistance.

The Secretary has long established intimate friendships with officers of sister institutions abroad, and with the aid now of the Society's linguists greetings in one's own tongue can be given each visitor.

Incidentally it should be remarked that both Mr. Cammen and Mr. Vera contribute to the Engineering Survey given monthly in THE JOURNAL.

The Secretary would consider it a privilege to arrange introductions for members going abroad and, vice versa, hopes in their foreign correspondence all members will encourage prospective visitors to America to expect a warm welcome at Society headquarters.

CALVIN W. RICE,
Secretary.

Council Notes

A MEETING of the Council was held on the afternoon of Friday, September 20, 1918, at Tarrytown, New York, at the home of Past-President Worcester R. Warner. There were present: Charles T. Main, *President;* H. de B. Parsons, Wm. H. Wiley, *Treasurer;* Worcester R. Warner, D. S. Jacobus, R. H. Fernald, C. T. Plunkett, John Hunter, Arthur M. Greene, Jr., James Hartness, John Stevens, L. P. Alford, *Chairman Meetings and Program Committee;* George A. Orrok, *Chairman Publication Committee,* and by invitation, Henry Hess, *Chairman Standardization Committee;* George H. Barrus, *Chairman Power Test Committee;* F. R. Low, *Chairman Advisory Board, Power Test Committee,* L. C. Marburg, representing the *Local Sections Committee,* and Calvin W. Rice, *Secretary.* This was the first meeting of the Council at which under the amendments to the Constitution voted in effect at the Spring Meeting in June, 1918, the Chairman of the Standing Committees of Administration had a seat in the Council.

BUSINESS FROM THE PRESIDENT

Committee on Aims and Organization. The President reported that as a result of conferences and suggestions from the Local Sections Committee, he had given his hearty approval to a suggested committee, similar to that appointed by the American Society of Civil Engineers, whose purpose it would be to discuss and formulate the aims and activities of the Society in the light of modern development and present-day thought and assist in finding an effective method of coöperation with the engineering profession for carrying out these aims. Following a report by Mr. Marburg, the President was empowered to appoint a committee on Aims and Organization, to be composed of one member from each Local Section and seven members at large.

STANDING COMMITTEES OF ADMINISTRATION

Finance Committee. The recommendation of this committee as presented in the Budget of date October 1, 1918, was approved, showing a total appropriation of two hundred and thirty-five thousand five hundred and thirty-five dollars ($235,535) for the fiscal year ending September 30, 1918.

Engineering Index. The Council approved the initiation of an engineering index as part of THE JOURNAL.

Meetings and Program Committee. The appointment of C. B. Auel, H. L. Whittemore, Byron Cummings, as members of the Sub-Committee on Protection of Industrial Workers, was approved.

Prof. Wm. Kent. A committee of three to prepare a memorial to Professor Kent was approved, to be appointed by the President.

Local Sections Committee. On recommendation of this committee, it was voted to approve the exchange of courtesies with the Los Angeles Engineering and Architects' Association.

The petition from the Cleveland members for authority to form a Section of the Society in Cleveland, as the mechanical-engineering section of the Cleveland Engineering Society, was also approved.

OTHER STANDING COMMITTEES

Standardization Committee. This committee was authorized as representing The American Society of Mechanical Engineers, to take definite and active steps to assist with the formation of the American Engineering Standards Committee.

Research Committee. The chairman reported that three of the sub-committees of this committee are at present very actively at work on the subjects of lubricants, bearing metals and flow meters, and it was hoped to organize in the near future some additional special committees.

PROFESSIONAL COMMITTEES

Screw Threads and Threaded Parts. The appointment of E. M. Herr, *Chairman;* E. H. Ehrman, *Vice-Chairman;* Stanley G. Flagg, James Hartness, A. M. Houser, Frank O. Wells as a Committee on Screw Threads and Threaded Parts was approved.

The duties of this Committee will be advisory, and its members will be ex-officio members of all of the existing committees considering screw-thread standards, and such existing committees will automatically become sub-committees of the new committee.

One of the functions of the committee will also be to follow the activities of other societies and governments in the work of screw-thread standardization and avoid duplication, and an effort will be made to bring together all interests and obtain results generally acceptable.

British Engineering Standards Association. In response to an invitation of the Association, asking that the Society coöperate in standardization of Milling Cutters and Small Tools, the President was empowered to appoint a committee for this purpose.

Boiler Code Committee. Interpretations Nos. 194, 195, 196, 197, 198, 199, and reopened cases 190 and 191, of this committee were accepted. They have been published in THE JOURNAL.

The printing of the revised Boiler Code was approved subject to the approval of the entire Boiler Code Committee.

Fire Hose Couplings. A suggested standardization of Fire Hose Couplings, with an invitation of the National Board of Fire Underwriters, was approved and referred to the President, with power to appoint a Committee on Fire Hose Couplings.

SPECIAL COMMITTEES

War Activities. The Secretary presented progress reports of the following War Activities Committee: War Industries Readjustment, Machine Tool Committee and Gages Committee.

APPOINTMENTS

By the President. George A. Orrok and F. R. Low to represent the A.S.M.E. on a Joint Journal Committee, of Engineering Council.

Council of (Women's) Organizations for War Service: Mrs. Chas. Ethan Davis.

National Safety Council, St. Louis, September 16 to 20, J. P. Calderwood, M. W. Alexander, C. M. Hansen, as Honorary Vice-Presidents.

Informal Corresponding Committee on Screw Threads with British Engineering Standardization Association. E. M. Herr, *Chairman;* E. H. Ehrman, *Vice-Chairman;* R. E. Flanders, F. O. Wells, L. V. Benet, appointed as a committee, to be called British Informal Corresponding Committee—which is designed to help screw-thread standardization work in an informal way through educational methods.

By the Council. Dr. W. F. M. Goss was appointed to fill the unexpired term of two years of the late Dr. F. R. Hutton on the John Fritz Medal Board of Award.

Dr. Ira N. Hollis was appointed Chairman of the Student Branch Committee.

Adjournment was taken to meet in Indianapolis on the occasion of the Joint Section Meeting of the Mid-Western Sections on October 25. (This meeting was later postponed on account of the epidemic of Spanish influenza.)

CALVIN W. RICE,
Secretary.

Organization and Proceedings of National Screw Thread Commission

THE Commission for the Standardization of Screw Threads, authorized by Congress in accordance with Act No. 10852 of the House of Representatives, of which mention was made on page 875 of THE JOURNAL for October, was formally appointed by the Secretary of Commerce on September 21, and has been divided up into the following committees:

1 *Pitches, systems, form of thread*—F. O. Wells, Com. S. M. Robinson, E. H. Ehrman, H. T. Herr, H. W. Bearce, secretary.
2 *Tolerances, classification*—James Hartness, E. H. Ehrman, Col. E. C. Peck, H. L. Van Keuren, secretary.
3 *Nomenclature and terminology*—F. O. Wells, Com. E. J. Marquart, Major O. B. Zimmerman, Robert Lacy, secretary.
4 *Gages and methods of test*—Col. E. C. Peck, James Hartness, Com. E. J. Marquart, H. L. Van Keuren, secretary.

Seven of the members of these committees are members of the Society, namely, Messrs. Wells, Ehrman, Herr, Hartness, Peck, Zimmerman and Lacy.

As stated in the bill, the duties of the Commission are to ascertain and establish standards for screw threads, which shall be submitted to the Secretary of War, the Secretary of the Navy and the Secretary of Commerce for their approval. These standards, when approved, shall be adopted and used in the manufacturing plants under the control of the War and Navy departments and so far as practicable in all specifications for screw threads in proposals for manufactured articles, parts or materials to be used under the direction of these departments. It is also intended by the bill that the Secretary of Commerce shall promulgate such standards for use by the public and publish the same as a public document.

The first hearing for the purpose of obtaining data and views from manufacturers and users of screw-thread products was held on October 7 in the Engineering Societies Building, New York City, at which the following topics were discussed:

1 As a national standard, is there any objection to the continua-

tion of the U. S. Standard system of thread diameters and pitches for general use in practically its present shape?

2 As a national standard, is there any objection to the adoption of the S. A. E. system of diameters and pitches of fine threads?

3 As a national standard, to what extent could the A. S. M. E. system of standard machine screws be adopted?

4 There seems to be a general feeling that in standardization we should make it possible to cover several classes of work and there has been suggested a minimum of four classes of fits to provide for different grades of work ranging from reasonably wrench-tight fits to very loose fits. Would such a classification, including at least four classes, be sufficient for all grades of work encountered in the various systems of threads previously mentioned or would a classification including more than four classes be required?

5 Is there any objection to adopting the "standard hole" practice for screw threads—that is, the practice of making all the taps for any particular thread of one basic size and securing the required fit by changing the diameter of the screw on male threaded work which is to assemble with the nut cut by the basic tap?

The consensus of opinion of those present was as follows:

1. The U. S. system should be continued practically in its present form for the ordinary threaded work, to which it is well adapted.

Objections were raised to its use for diameters less than ½ in. on the ground that for small work the U. S. pitches are too coarse and the threaded work too much weakened by excessive depth of thread.

2. The S. A. E. system is satisfactory for use where finer threads are necessary, as, for example, in automobile aud aeroplane work.

3. The A. S. M. E. machine-screw system should be used to supplement the U. S. system for diameters less than ¼ in., and all sizes from 14 to 30 should be discontinued in order that there may be no overlapping of the two systems. A minority thought that all A.S.M.E. sizes should be retained.

4. Classification of Fits. The general opinion was that four classes of fits would be ample to provide for all ordinary threaded work, and that very probably three classes would be sufficient, since it was felt that wrench fits, stud fits, etc., which could not be covered by general specifications should be classed as "Special," and no attempt made to include them in the regular classification.

5. Standard Hole Practice. There was a sharp difference of opinion on the question of whether the nut or the screw should be made basic, with the majority favoring the former.

A part of the objection to making the hole basic arose from a misapprehension. It was suggested that if the tap or the tapped hole were made basic it would be necessary to carry in stock several sizes of bolts in order to provide for different classes of fits. Such, however, is not the case, since in general only a single class of fit will apply to each threaded product, and only that class would be carried in stock. For example, machine screws should be made within certain tolerances, while bolts for agricultural machinery would require larger tolerances, and there would be no necessity for providing for machine-screw fits on agricultural-machinery bolts, or for "agricultural fits" on machine screws.

A second hearing was held in New York on October 21. Further hearings will be held at New York, Dayton, Detroit, Washington and other places as may be advisable, and manufacturers and users of screw-thread products are invited to attend the various hearings. Those desiring to be present should submit their intention in writing, together with a statement covering the points they wish to bring to the attention of the Commission.

After sufficient information is secured from the manufacturers and users, the Commission will decide upon the screw-thread systems to be promulgated for use as national standards and will recommend tolerances for the interchangeable manufacture of various threaded products in which the standard thread systems are used.

Ambrose Swasey's Second Gift to the Engineering Foundation

To his original gift to the United Engineering Society of $200,000 for engineering research, which made possible the establishment of the Engineering Foundation, Mr. Ambrose Swasey, Past-President Am.Soc.M.E., has added $100,000. This splendid gift, making a total of $300,000, is an expression of Mr. Swasey's appreciation of the war service already rendered by the Engineering Foundation; and of his belief in the urgent need for research in applied science in this country.

The following appreciation of Mr. Swasey's generosity has been received from the Trustees of the United Engineering Society and the Engineering Foundation:

Said Plutarch a long time ago, "To appreciate a man's work at the full it is well to know the man himself, his circumstances and the incidents of his career." He might as truly have said "gift" instead of "work."

Ambrose Swasey, engineer, collaborator with scientists, promoter of engineering research, patron of the Engineering Foundation, advancer of the good of mankind, modest gentleman and generous giver, is, happily, well known to a great many engineers, who will therefore more fully appreciate his recent additional gift, for the use of the Engineering Foundation, the purpose of which is "the furtherance of research in science and engineering, and the advancement of the profession of engineering and the good of mankind."

But full appreciation of a gift of money necessitates more than acquaintance with the giver and knowledge of the amount. Its timeliness; its inspiration; the character and continuity of its benefits, all must be comprehended. But whose imagination, though far-visioned as the great telescopes Mr. Swasey has built, can see the limits of benefit of such gifts as he has made to the Engineering Foundation, attracting—as they will—other gifts and evidences of devotion to a great cause? Every such gift lays responsibilities upon the recipients. Will American engineers grasp not merely their pecuniary value but also emulate the spirit of fraternity and desire for harmony which have accompanied them? Shall we not work together and with Ambrose Swasey to advance still further the good of mankind, thus to demonstrate an acceptance of our obligations to humanity which is a counterpart in a democracy of the *noblesse oblige* of aristocratic tradition?

Timeliness is a wonderful feature of Mr. Swasey's gifts. The first was made in the early stages of the present struggle of the nobler elements of the world against the ignoble, which has come to be "the people's war." It enables the Engineering Foundation to join with the National Academy of Sciences in responding to the President's request to bring into coöperation governmental, educational, industrial and other research agencies in the interest of the national defense and scientific and industrial research, by establishing the National Research Council. This council of scientists and engineers has already a fine record of achievement.

To his first large gift, the principal of which is still intact, Mr. Swasey has now added generously at another psychological moment. As the great conflict seems nearer an end, there lies immediately before humanity a great era of physical reconstruction, and, vastly more, an era of spiritual advancement and elevation such as has never yet been experienced. Many of the problems of human relationships, of justice and of mercy, await the genius of the engineer for their solution, quite as much as do the tasks of construction and the development of physical resources. Let us go forward with Ambrose Swasey into the fields of opportunity. Let differences be put aside and a united, mighty effort be exerted for the advancement of the engineering profession and of mankind.

ALFRED D. FLINN, *Secretary*,
United Engineering Society and Engineering Foundation.

A Society badge found in a public building in Philadelphia has been received at Society's headquarters. Further information may be obtained by addressing the Secretary's office.

ANNUAL MEETING PROGRAM

New York, December 3 to 6, 1918

(Tentative; Other Papers to be Announced Later)

Tuesday Evening, December 3

Report of Tellers of Election and Introduction of the President-Elect

Presidential Address, followed by Reception

Wednesday Morning, December 4

Business Meeting: Amendments to Constitution; Reports of Standing Committees of Administration and Standing Committees; Reports of Special Committees, including Standardization of Flanges and Pipe Fittings

Preliminary Report of the Committee on Aims and Organization

Wednesday Noon

Luncheon and Address by Dr. George W. Kirchwey, formerly Dean of Columbia Law School, on A Message from the Legal Profession

Wednesday Afternoon (Simultaneous Sessions)

MACHINE-SHOP SESSION

Measurement of Thread Gages, H. L. VanKeuren

Standards for Large Taper Shanks and Sockets, Luther D. Burlingame

It is also expected that reports will be presented on the work of the British Engineering Standards Association

In connection with this session, the Bureau of Standards has arranged for an exhibit of the measuring apparatus and methods of the Bureau in testing screw-thread gages.

JOINT SESSION ON REFRIGERATION

The American Society of Refrigerating Engineers will join with this Society in a session on Refrigeration, with the following subjects:

Refrigerating Plant Efficiency, Victor J. Azbe

Topical Discussion on Fuel Economy in Refrigerating Plants

GENERAL SESSION

Weights and Measures of Latin America, Frederick A. Halsey

Papers on Management, with particular reference to the U. S. Shipping Board

Wednesday Evening

Lecture on The Achievements of Naval Engineering in the War by William L. Cathcart, Lieutenant-Commander, U. S. N. R. F.

Thursday Morning, December 5

Keynote Session on the general subject of Engineering of Man Power

Papers and addresses will be contributed to this session on: Organization; Standardization and Administration of Wages; Non-Financial Incentives; Incentive of Control in Industry; Employment of Labor; Dilution of Labor; Intensive Training; Human Relations in Industry

Thursday Afternoon (Simultaneous Sessions)

KEYNOTE SESSION

Continuation of morning session on the general subject of Engineering of Man Power

TEXTILE SESSION

Industrial Power Problems, W. F. Uhl

Properties of Airplane Fabrics, E. Dean Walen

Daylight vs. Sunlight in Sawtooth Roof Construction, W. S. Brown

Factory Stairs and Stairways, G. L. H. Arnold

GAS-POWER SESSION

The Cooling Losses in Combustion Engines as Affecting Design, C. A. Norman

Discussion of Certain Problems in Regard to Marine Diesel Oil Engines, J. W. Anderson

This session will be largely devoted to a discussion of the subject of oil engines

Thursday Evening

Motion pictures relating to the technical side of war; dancing will follow

Friday Morning, December 6 (Simultaneous Sessions)

POWER-PLANT SESSION

The Conservation of Heat Losses from Pipes and Boilers, Glen D. Bagley

Chemical and Physical Control of Boiler Operation and Application of Simple Formula for Estimating the Heat-Loss Items, E. A. Uehling

GENERAL SESSION

The Relative Corrosion of Alloys, R. B. Fehr

The Relative Merits of Cast-Iron, Wrought Iron and Steel Pipe for House Drainage Purposes, Wm. P. Gerhard.

The Design and Maintenance in Operation of Hydraulic Valves and Fittings for Use with Pressures from 1000-8000 Lb. Per Sq. In., Wm. W. Gaylord

Mechanical Features of the Vertical-Lift Bridge, Horatio P. Van Cleve

INDIANAPOLIS MEETING POSTPONED

Although the ban on public meetings was about to be removed in Indianapolis at the time the Council meeting and the meeting of the Mid-Western Sections was scheduled to be held in that city, October 25 and 26, it was nevertheless considered advisable to postpone the event to a later date.

The meeting is tentatively scheduled for November 15 and 16 and members will receive individual notice. If this arrangement can be made, the Indianapolis committee will endeavor to carry through the program as arranged for the original meeting. The program of the meeting was as follows:

First Day

9:30 a. m. Registration at Claypool Hotel.

11:30 a. m. Meeting of the Committee on Local Sections and members of the Executive Committees of the Mid-Western sections.

12:30 p. m. Informal luncheon at the Claypool. The Mayor of Indianapolis will welcome the visitors and President Main will respond.

2:00 p. m. Symposium on Fuel Conservation:

Session opened by Professor Charles Russ Richards, Dean of the College of Engineering and Director of the Engineering Experiment Station of the University of Illinois.

An explanation of the Regulations of the Fuel Administration, by Dr. P. B. Noyes, Director of Publicity and Information, U. S. Fuel Administration.

What the Fuel Administration Expects of the Engineer, by David Moffat Myers, Advisory Engineer, U. S. Fuel Administration.

Fuel Economy on the Railroads, by Major E. C. Schmidt, of the Railway Fuel Economy Division.

Discussion, in which the Administrative Engineers of the Fuel Administration and members of the Society will participate.

Storage of Coal, by Prof. H. H. Stoek, University of Illinois.

6:30 p. m. Informal dinner, at which nominee for President M. E. Cooley, is expected to speak, followed by war pictures.

Second Day

9:00 a. m. Symposium on Research.

Opening addresses by Profs. Arthur M. Greene, and Walter Rautenstrauch, members of the Society's Committee on Research.

Address by Mr. C. E. Skinner, Engineer, Research Division, Westinghouse Electric & Manufacturing Co. on Organized Research in Connection with the Industries.

Address by Dr. W. J. Lester, Vice-Chairman of the Engineering Division, National Research Council.

Paper to be submitted by Dr. H. M. Howe, Chairman of Engineering Division of the National Research Council.

Discussion by members of the Society.

12:30 p. m. Informal luncheon at place arranged by the Local Committee.

2:30 p. m. Visit to Nordyke & Marmon's plant to witness the manufacture of the Liberty Motor.

AMONG THE SECTIONS

The Committee on Local Sections gives the following information to the Local Executive Committees on the subject of formulating local constitutions and by-laws in conformity with the national by-laws governing Local Sections which have been in successful operation since October 1917.

These national by-laws were the result of two years' work on the part of the major committee, and they were framed with the object of covering all the variety of conditions existing in the several centers, and at the same time affording opportunity to the individual Sections to carry on activities of local interest.

To date a number of the Sections have given attention to this matter of constitution and by-laws, and for the benefit of the other committees who might like to institute this piece of work the Committee on Local Sections drafted a blank form of constitution which has been sent to all the Sections through the medium of the record books of their chairmen and secretaries.

It is interesting to review some of the documents which govern the Local Sections' activities. It should be noted that in some cases the coöperation is so close that the name of our Section has been written in the local society constitution.

The By-Laws of the Affiliated Technical Societies of Atlanta antedate our national by-laws, having been adopted in 1913. The fundamentals of this organization are that the local sections of the national engineering societies and the Chemical Society and the Engineering Association of the South have equal rights and privileges. The by-laws are brief, governing the executive committee and the order of business at the meetings. All the members of the participating organizations are included as members of the Affiliated Association.

The document of St. Louis exemplifies very forcibly the unification and coöperation of all the Societies in that important center. The Association is managed by a Council on which are represented the Engineers' Club and each of the affiliated societies. This Council has jurisdiction over all matters of joint interest in so far as its decisions shall not conflict with the rules of the individual societies. The constitution provides for the joint action on all local public affairs presented for consideration to any one or more of the societies. It also provides for action on national public affairs, and the Council is empowered to refer questions to the consideration of one or more national engineering bodies through their affiliated societies. In all the other articles of the constitution which cover meetings, dues and services the idea of joint action on all matters predominates.

The constitution of the Birmingham Section was adopted in March 1916 and provides inclusively for the organization of the Birmingham Section. The document states that the objects of the local Section shall be the professional improvement of the members of the A.S.M.E. residing in and near Birmingham; the encouragement of social intercourse among them, the advancement of engineering in its several branches, the advancement of the engineering profession in the opinion of the general public, and the influencing in a dignified manner of the solution of public questions involving engineering and scientific consideration. The constitution provides for membership, for officers and their duties, for the annual and monthly meetings, and for amendments.

The Indianapolis Section, which is only two years old, has already a very complete constitution and by-laws, very similar to that of Birmingham in the statement of objects of the Section, in the membership, the officers, and meetings. The by-laws provide for the order of business at the meetings, for the nomination of officers, and for the parliamentary standards.

The New York Section operates under a constitution only, which was adopted on May 1, 1918. The constitution is brief, and its articles cover the name of the section, membership, officers, nominations and miscellaneous.

Philadelphia has been considering a constitution this summer, and a draft of the proposed constitution was presented at its September meeting. The significant feature of the Philadelphia constitution is the provision for the Executive, Papers, Meetings, Public Relations, Research, Nominating, Auditing and Membership Committees. The organization in Philadelphia, therefore, is more nearly comparable with the organization of the parent Society, and the suggestion this document develops is that it may be desirable to encourage the local executive committees to form sub-committees parallel with the committees of the major organization with a view to increasing the inter-committee relations of the parent society, and thus contribute very materially to the strength of the organization.

Minnesota has also drafted a constitution which is now under consideration for adoption. The document itself states that it has been drawn up "to cover in detail the peculiar organization which has been developed for the Minnesota Section and its particular purpose is to form a guide for future work so that activities can be carried along with uniformity." The article on membership provides for local members who are not members of the A.S.M.E. and includes members of the Student Branch in the State of Minnesota as full members of the Section. In the article entitled Activities the object of the Section is stated to be for the holding of meetings for the presentation and discussion of papers relating to engineering, and to the allied arts and sciences, and also for holding meetings of social intercourse, and making trips to plants engaged in engineering enterprises.

In all the constitutions formulated so far, there is a significant element of individuality. The provision of the national by-laws is that local sections may frame their own rules, but they should conform as far as possible with the spirit of the national rules. The various interpretations of these sentiments by the local committees are interesting, and it is to be hoped that soon each one of our twenty-two sections will adopt a form of by-laws which will most nearly meet its local needs.

Section Meetings

BIRMINGHAM

October 24. The program for this event of the local society, held at the Birmingham Civil Association's rooms, was under the auspices of the Birmingham Section. E. H. Rosseau, chief engineer of the Birmingham Machine & Foundry Co., delivered an interesting and timely paper, illustrated with balopticon views, on The Manufacture of Raw Sugar. The meeting was followed by a buffet lunch.

JAMES W. MOORE,
Secretary.

BOSTON

October 17. A meeting of the Section, together with the Boston members of the A.I.E.E., A.S.C.E., Waterworks Association, Worcester Section, Providence Engineering Society, and the Manufacturers' Association of Eastern Massachusetts, was held in Lorrimer Hall. Magnus W. Alexander, Mem.Am.Soc.M.E., read a paper on The Elements of the Labor Problem.

ELMER SMITH,
Secretary.

CHICAGO

October 28. A joint meeting with the Chicago Section of the A.I.E.E. was held, the subject being Illumination. A paper was read by Professor Clewell.

ARTHUR L. RICE,
Secretary.

CLEVELAND

October 4. The newly established Section organized with the following officers: E. S. Carman, *Chairman;* J. H. Stratton, vice-chairman; J. H. Herron, secretary, and Willard Brown, treasurer.

J. H. HERRON,
Secretary.

INDIANAPOLIS

October 25-26. The joint meeting of the Council with the mid-western sections has been postponed, due to the influenza epidemic.

CHARLES BROSMAN,
Secretary.

LOS ANGELES

The Los Angeles Section united with the Technical Societies of Los Angeles in an official effort to assist the fourth Liberty Loan. This definite act on the part of the profession should be the forerunner of future nation-wide organization for civic welfare.

T. J. ROYER,
Secretary

CONNECTICUT
(New Haven Branch)

October 9. This meeting was postponed due to the influenza epidemic.

E. H. LOCKWOOD,
Secretary.

MINNESOTA

October 7. A meeting was held at the rooms of the St. Paul Association. Dinner was served at 6.30 and there were 40 members and guests present. F. W. Speer, Jr., Chief Chemist of the H. Koppers Co., Pittsburgh, read a paper on By-Product Coking, Particularly in Its Relation to the Steel and Iron Industry. Mr. Speer gave a short history of the development of the coke industry. Then by means of a series of lantern slides he described a complete by-product coke plant, and told in a very concise manner how the coke is produced and the by-products conserved. The lecture was followed by a lively discussion.

Among the guests were Capt. L. P. Riggins, Lieut. B. A. Meixner, and Lieut. J. J. Hanson, of the Ordnance Department, U. S. A.

RAY MAYHEW,
Secretary.

NEW ORLEANS

October 14. The Section held its monthly meeting in conjunction with the Louisiana Engineering Society.

E. W. CARR, JR.,
Secretary.

NEW YORK

September 28. At the invitation of Mr. John Hunter, a member of the Council and naval constructor of the Standard Shipbuilding Corporation, members of the Section were guests of the company on the occasion of a double launching at the Shooter's Island yard, Staten Island, of two 7500-ton vessels, the steamships Monmouth and Dallas. Probably 750 men and women participated and the company provided two commodious excursion steamboats to carry the party between the Battery and the shipyard, and tendered an unexpected collation after the launching.

H. D. EGBERT,
Secretary.

PHILADELPHIA

September 24. The initial meeting of the 1918-1919 season was held at the Engineers' Club. The address of the evening was given by W. H. Blood, Jr., of the American International Shipbuilding Corporation, on The Making of Hog Island, the Greatest Shipyard in the World. This address was illustrated with many lantern slides, and film showing the launching of the first vessel from that yard.

At this meeting the proposed by-laws for the government of the Section, mentioned above, were submitted.

October 22. This meeting was postponed, due to the influenza epidemic.

J. P. MUDD,
Secretary.

ST. LOUIS

September 27. The first of the fall meetings was held in the Daniel Boone room at the Statler Hotel, preceded by a dinner. J. A. Whitlow, Administrative Engineer of the United States Fuel

October 23. This meeting was postponed, due to the influenza epidemic.
J. P. Morrison,
Secretary.

SAN FRANCISCO

September 26. As reported in the October Journal, a joint meeting of the local section of the A.S.C.E., A.S.M.E., A.I.M.E., A.I.E.E. and A.C.S. was held in the Engineers' Club, under the auspices of the local section of this Society.

The subject was Fuel Conservation, and consisted of a Symposium by the following speakers:

Albert E. Schwabacher, U. S. Fuel Administrator for California, Fuel Conservation; A. H. Markwart, Civil Engineer, Production of Energy; D. M. Folsom, U. S. Fuel Administration, Oil Division, Future Requirements of Oil; John A. Britton, V. P. and General Manager, Pacific Gas & Electric Co., The Use of Gas as a Conservation Measure; H. G. Butler, Power Administrator, Electric Consolidatioins and Their Relation to Fuel Conservation; P. M. Downing, Chief Engineer Electric Department, Pacific Gas & Electric Co., Sources of Energy Supply; Harry S. Markey, Mem. Am. Soc. M. E., District Steam Heating as Related to Fuel Conservation; Major George F. Sever, War Industries; W. J. Davis, Pacific Coast Engineer, General Electric Co., Railroad Electrification as a Fuel Conservation Measure; and Professor Edmund O'Neill, Mem.A.C.S., The Chemical Side of Fuel Conservation.

The reading of these papers was followed by a general discussion.
George L. Hurst,
Secretary.

Student Branches

The new military program as outlined by Secretary Baker calling for an increase of the Army by more than two million men by July 1, 1919, has vitally affected the technical colleges throughout the country. Since the students are not in any sense in a deferred or favored class, and will practically all be assigned to active service within the next year, schools and colleges obviously must undergo fundamental changes in school practice in order to render effective service.

In about 550 institutions Students Army Training Corps have been established, and these institutions will therefore cease to function as purely academic universities and will become a part of the Nation's war machine. The object of establishing these units is to utilize effectively the plant, equipment and organization of the colleges for selecting and training officer-candidates and technical experts for service in the existing emergency.

The Corps is divided into two sections, the Collegiate (or "A") Section and the Vocational (or "B") Section. The units of the "B" Section were formerly known as National Army Training Detachments. They aim to train soldiers for service as trade specialists in the Army.

The "A," or Collegiate Section, inaugurated October 1, is open to registrants who are members of some authorized college, university or professional school. Students of authorized institutions may join the Students Army Training Corps by voluntary induction into the service. They thus become members of the Army on active duty, receiving pay and subsistence, subject to military orders, and living in barracks under military discipline in exactly the same manner as any other soldier.

The housing, subsistence and instruction of soldiers in both branches of the Students Army Training Corps is provided by educational institutions under contraett with the Government.

The members of the Students Army Training Corps are voluntarily inducted into the service, and are ordinarily allowed to choose the branch of the service for which they wish to be prepared. This freedom of choice, however, is not absolute. It depends upon the individual's qualifications and upon the needs of the service at any particular time. The status of a member of the Students Army Training Corps is that of a private.

Members of the Students Army Training Corps, having already been inducted into the service, will not come under the operation of the Selective Service Law. It is expected that the members of Collegiate Sections will be transferred from institutions every three months in age groups, the twenty-year-old men going first, the nineteen-year-old men going next, and the eighteen-year-old men last, roughly corresponding to the period at which men of these ages will be called under the Selective Service Law. As these groups leave the colleges their places will be taken by new contingents obtained by individual induction, or, if necessary, in depot brigades. Students of such subjects as engineering, chemistry and medicine may be required to finish their courses where the needs of the service make this desirable.

Members of Vocational Sections will ordinarily remain at the institution for two months and will then be assigned to various branches of the service in which technicians are needed.

In addition to 11 hours per week of military training the course of study in the Collegiate Section of the Students Army Training Corps will consist of the ordinary college or technical courses grouped and modified in such ways as are necessary to meet the needs of the War Department.

Members of Vocational Sections will pursue such subjects as auto-driving, auto-repair, bench woodwork, sheet-metal work and electrical work, etc., in addition to 13½ hours per week of military training.

Members of both sections will attend courses on the Issues of the War.

At certain specified institutions, a limited number of registrants may, upon indicating their preference, be inducted into the Navy or the Marine Corps. Such men will wear naval uniforms, and pay their own expenses individually from an allowance made to them by the Navy Department. The Naval and Marine Sections will attend all drills and exercises of the Students Army Training Corps.

In this new development the Committee on Student Branches hopes there will be an opportunity for furthering the work of the Student Branch Organization. If the very full curricula preclude the holding of meetings of Student Branches it is hoped a skeleton organization with regularly appointed officers will be formed in order that the privileges of Student Branch membership may be obtained.

Society Donates Rooms to War Department

As a policy, the Society has no "slacker" rooms at its headquarters. The Committee on Education and Special Training, directing the Students' Army Training Corps, numbering 150,000 men in the principal colleges of America, are now the Society's guests and occupy the Members' Reception Room and the Council Room as headquarters for the Second District of the Committee.

Recently also the Congressional Commission on Standardization of Screw Threads has met in the Society's rooms. The Council considers it an honor to have headquarters freely used by the Government or by committees of other societies—in fact, *Service to the Utmost* is the Society's motto.

NECROLOGY

WILLIAM KENT

In the death of William Kent on September 18, announcement of which was made in the last number of The Journal, the Society has lost a member who will be sadly missed by a very large number who have regularly met him at the Society's meetings, or have come in contact with him in a professional way.

Mr. Kent was an organization member of the Society, and Vice-President from 1888 to 1890. He was preëminently versatile, an original thinker, a ready speaker, an author and frequent contributor of papers and technical articles, and an engineer whose services were much in demand in a consulting capacity or as an expert in patent cases. He was a regular attendant at the Annual and Spring Meetings, and probably contributed more largely to the discussion of the various papers than any other member, besides being the author of no less than 12 papers, a number of which were noteworthy contributions to engineering knowledge.

As the author of the Mechanical Engineers' Pocket-Book his name became known among engineers the world over, and through this medium he rendered an almost incalculable service to the engineering profession. For many years Mr. Kent had followed the practice of clipping and filing data on engineering subjects, and this material was made the basis of the first edition of his book in 1895. At that time practically the only American engineering pocketbooks were Trautwine, in the civil engineering field, and Haswell, largely mechanical, but dealing with engineering of an earlier day when rule-of-thumb rather than research was the main reliance. In Kent's book the practice was followed of summarizing the data and giving the sources of authority, so that any of the subjects could be investigated further.

William Kent

William Kent was born in Philadelphia on March 5, 1851. He was educated in the schools of that city, and later, while employed with the Jersey City Gas Company, he attended the night classes of Cooper Union for a period of five years. He then became connected with the blast furnace of Cooper, Hewitt and Company, Ringwood, N. J., where he remained until 1874. Becoming convinced of the necessity of further education, he entered Stevens Institute of Technology, first as a special student in chemistry, and later, at the instance of the late Dr. Robert H. Thurston, enrolled himself in the senior year class, graduating in 1876 with the degree of mechanical engineer. During his senior year he engaged upon investigations for Dr. Thurston upon the alloys of copper. During 1884-1885 he was president of the Alumni Association of the Institute.

From 1877 to 1879 he was editor of the *American Manufacturer and Iron World* of Pittsburgh, resigning to become superintendent of the open-hearth plant of the Schoenberger Steel Company. Leaving the steel business he took charge of the Babcock and Wilcox Company's Pittsburgh office, later being transferred to the New York office. While with this company he made numerous inventions on boilers, furnaces and boiler accessories. In 1887 he became general manager of the Spring Torsion Balance Scale Company and developed the methods and machinery for building this highly sensitive scale.

In 1891 Mr. Kent began the practice of consulting engineer and in 1895 became associate editor of *Engineering News*, a connection continued until 1903, at which time he was offered and accepted the position of dean of mechanical engineering in the L. C. Smith College of Applied Science in Syracuse University. He remained at Syracuse until 1908, when he became general manager of the Sandusky Foundry and Machine Company, Sandusky, Ohio. In 1910 he resumed his consulting engineering practice and at the same time became contributing editor to *Industrial Engineering*.

Besides his Mechanical Engineers' Pocket-Book, Mr. Kent was also the author of Steam Boiler Economy, Investigating an Industry, Bookkeeping and Cost Accounting for Factories, as well as papers presented before the numerous technical societies of which he was a member, and articles contributed to the technical press. He was a lecturer at many colleges and technical schools, including Yale, Cornell, University of Illinois, West Virginia University, Stevens Institute, Brooklyn, Franklin and Worcester Polytechnic institutes, and many others.

Mr. Kent was regarded as an authority on steam-boiler practice and on shop management. He was an earnest advocate of the principles of scientific management as enunciated by Frederick W. Taylor and was one of the charter members of the Taylor Society. He was also an inventor and designed the wing-wall furnace to secure complete combustion where there was not room for the Dutch-oven furnace, and developed a gas producer similar to the Dawson, but entirely independently of the latter. Singularly, his American patents and the English Dawson patents were issued on the same day. Many other inventions and devices are to his credit.

He also was engaged upon numerous investigations, notably work for the Babcock and Wilcox Company on high-volatile coals, for the New York Edison Company on smoke abatement, and in New Jersey with regard to certain water rights. Latterly he devoted much of his time to patent cases as an expert.

Besides his membership in this Society, he was a member of the American Society of Heating and Ventilating Engineers, of which he was president in 1905; American Institute of Mining Engineers; Society for the Promotion of Engineering Education; American Association for the Advancement of Science, and a number of others. He was a member of the Power Test Committee of the A.S.M.E. In 1907 he received the degree of Doctor of Engineering from Syracuse University. He is survived by his wife, one daughter and two sons, Robert Thurston Kent, and Lieut. Edward R. Kent, U. S. A., both engineers.

A. C. BEESON

A. C. Beeson was born in Salem, Ohio, on February 26, 1845. He was educated in the "village schoolhouse" there, obtaining in

addition a fair knowledge of mechanics in his father's machine shop. His first employment was at Pithole, Pa., in 1865, where he engaged successively in pumping and drilling wells. It was not until 1868 that the opportunity, which proved to lead to his life's work, came to him when he was engaged as gauger by the Titusville Pipe Co. and assigned to duty in the Pleasantville district. In June 1870 he entered the service of Vandergrift & Forman and constructed a pipe line from White Oak Station, now Trunkeyville, to Fagundas. The rapid extension of the oil fields in the early seventies was accompanied by unusual activity in pipe-line construction and Mr. Beeson was called on to construct pipe lines in districts of widely separated localities.

When Vandergrift & Forman organized the Fairview Pipe Line, the piping system was vastly extended under Mr. Beeson's direct supervision. He remained with this company and its successor, the United Pipe Lines, until 1885, when he purchased and took charge of a natural-gas plant in the lower-country oil towns. In 1889 he disposed of his gas interests and returned to the pipe-line industry as superintendent of the Western & Atlantic Pipe Line with headquarters in Pittsburgh. He was appointed superintendent of the Indiana Pipe Line upon its organization in 1899 and later vice-president, which position he held at the time he was taken ill. He died on September 10, 1918. He became an associate-member of the Society in 1914.

W. A. BLONCK

W. A. Blonck was born on April 30, 1872, in Wriezen, Germany. His early education he obtained in the Real Gymnasium of Wriezen, later receiving the degrees of M. E. and E. E. from Mittweida, Saxony, in 1893.

His first position was with the Royal Saxon Railways, Dresden, on construction work of transmission lines in connection with a three-phase power station for Dresden depots. In 1894 he was employed by Körting Brothers, Hanover, Germany, to design electric machinery and apparatus, and the following year he was connected with Siemens and Halske, Magdeburg, Germany, on the estimates and supervision of construction of isolated factory plants. From 1896 to 1901 he was with Ganz & Co., Budapest, Austria-Hungary, working on estimates and supervision of construction of steam and hydraulic municipal plants in Bulgaria, Hungary and Austria. In 1901 he came to the United States and for about a year was with the Chicago Edison Co., Chicago, Ill., on the preliminary work of the design of the large Fisk Street power plant. From 1902 to 1904 he was associated with the Arnold Electric Power Station Co., Chicago, when he became electrical engineer in charge of construction and operation for the Chicago and Milwaukee Electric Railroad Co. The years from 1905 to 1912 he had consulting offices in Chicago where he specialized on reports, design and construction of railway, light and industrial plants. In 1912 he became president of the W. A. Blonck Co., Inc., Chicago, which position he occupied at the time of his death, January 14, 1918.

Mr. Blonck was particularly interested in the development of the boiler efficiency meter and upon his submitting his investigations and tests in that connection to The Franklin Institute, received a Certificate of Merit for establishing graphically the zero method of best boiler efficiency. He also conducted special investigations of boiler-furnace operation and definite methods of doing away with guesswork in the fire room. He became a member of the Society in 1916.

ROBERT MUNN DIXON

A Tribute by The Secretary

Robert M. Dixon, for 31 years a member of The American Society of Mechanical Engineers and the chairman of its Finance Committee, died suddenly at his home at East Orange, N. J., on October 17, 1918. His death came as a great shock to his many friends, as he had been at business regularly and apparently had been in his accustomed health and had attended to his affairs with his usual energy and attention to their many details up to the very date of his passing away.

Robert M. Dixon

It has been the writer's privilege, as Secretary of this Society, to be intimately associated with Mr. Dixon in relation to its numerous activities where his sound judgment and constructive suggestions were not only helpful, but of the greatest intrinsic value.

His interest in the Society as an organization was deep-seated and very real, and it would be impossible to give an adequate appreciation of the service which he rendered. He served on the Finance Committee for ten years, for over eight years as chairman. During this period, the income of the Society was nearly doubled; the indebtedness occasioned by the acceptance of the Carnegie gift of the Engineering Building, nearly $100,000, was paid off and the cash surplus of the Society brought up to an excess of $100,000.

It was a part of Mr. Dixon's financial policy and direction that in so responsible and important a work as the Society is undertaking, it should accumulate as an essential part of that responsibility a sufficient cash surplus to provide for unforeseen and unprovided-for expenses of administration (as publications, meetings, etc.) so that their future would be assured beyond any possible doubt.

The Society is one-fourth owner and administrator of real estate worth $2,500,000, besides the publisher of its annual volume of Transactions and the monthly Journal, costing annually $100,000.

In this capacity as chairman of the Finance Committee, Mr. Dixon was a most faithful attendant upon the meetings of the Council, invariably contributing the broadest concept of the Society's duties and recognizing that the technical and even the ethical success of the Society is to a large degree dependent upon a sound financial administration.

The bringing up, therefore, of the Society from a position of lesser importance relatively, both in its membership and in its financial standing, to that of the sister professional societies, to that of one of the leading professional societies of the United States, is a work deserving of the highest praise, and to its success Mr. Dixon contributed conspicuously.

Robert M. Dixon was born at East Orange, N. J., September 19, 1860, in the house where he lived at the time of his death. He was educated in the public schools and graduated from Stevens Institute of Technology in the class of 1881, with the degree of M. E. Subsequently, he took a great deal of interest in the affairs of the Institute, was elected president of the Alumni Association for the period 1898-1899, and was an alumni trustee from 1890 to 1893.

His engineering work began with the Delaware Bridge Company, of Trenton, N. J., where he was employed for two years until March 1883, when he was made assistant engineer of the Pintsch Lighting Company, which was merged with the Safety Car Heating and Lighting Company in 1887, with Mr. Dixon as chief engineer. He was elected vice-president of the Safety Car Heating and Lighting Company, January 15, 1902, and was made president of the company in May 1907, which office he was holding at the time of his death.

Mr. Dixon spent the greater part of his life in the field of railway-car heating and lighting, and was identified with the early application of steam from the locomotive for heating railway passenger cars and with the development of gas and electricity for lighting railway cars. He was also active in the field of harbor and coast lighting.

He was elected on the Board of Trustees of the United Engineering Society, as representative of this Society, December 1917, and was also member of the Finance Committee of the United Engineering Society.

Mr. Dixon gave a great deal of attention to railroad matters and was active as an executive officer of the New York Railroad Club from its earliest days as a club of railroad men. He served as treasurer of the club from 1903 to the time of his death. He was formerly chairman of the finance committee of the club, and was a member of its executive committee for 35 years.

WILLIAM J. KEEP

William J. Keep, for many years consulting engineer for the Michigan Stove Co., Detroit, and one of the best-known writers of the country on foundry topics, died on September 30 following an accident, when he was knocked to the pavement by a street car and sustained fatal injuries.

Mr. Keep was born in June, 1842, in Oberlin, Ohio. He attended Oberlin College for his freshman and sophomore years and was graduated from Union College, Schenectady, N. Y., in 1865, with the degree of civil engineer. He served an apprenticeship with the Globe Iron Works, Cleveland, and obtained his shop experience with Fuller, Warren & Co., Troy, N. Y. From 1865 to 1868 he was employed by Hubbell & Brothers, Buffalo stove manufacturers, when he became associated again with Fuller, Warren & Co. and was with them for about eight years. During the years of 1872 to 1877 he delivered a course of lectures to the senior class of Rensselaer Polytechnic Institute. From 1875 to 1881 he manufactured stoves on his own account in the city of Troy.

In 1902 his treatise on Cast Iron was published, which is the best known of his writings. In 1885 Mr. Keep brought out some results of his studies of the relation between the shrinkage of

William J. Keep

cast iron and the composition of a foundry mixture. Later he devised a method and apparatus known as "Keep's Test" which he later named "Mechanical Analysis," for the determination of shrinkage in cast iron, and in this way to regulate the cupola mixture. For this purpose he used a ½-in. test bar. He elaborated his method of testing after making many thousands of tests in the investigation of the relation between the chemical analysis of cast iron and its physical properties, and the results were embodied in his writings.

Mr. Keep became a member of our Society in 1893 and from 1903 to 1905 was vice-president. He was also a member of the American Institute of Mining Engineers, the (British) Iron and Steel Institute, the International Association for Testing Materials, the American Foundrymen's Association, the American Association for the Advancement of Science, the Detroit Engineering Society (Past-President), honorary member of the Rensselaer Society of Engineers, and The Franklin Institute.

ROLL OF HONOR

DIED IN THE SERVICE

Walter Antosch, Chief Machinist, U. S. S. Westbridge, U. S. Navy.

Arthur H. Burges, Sergeant, 23d Engineers, U. S. Army, American Expeditionary Forces, France.

William R. King, Major, Ordnance Department, U. S. Army, Aberdeen Proving Ground, Md.

The following list of those in the Service is made up of the names of members of the Society sent in during the month of October. The number of stars in the service flag is now over 1100.

Abbott, Edward R., Captain, Chemical Warfare Service, U. S. Army.

Armstrong, Walter J., Captain, Ordnance Department, U. S. Army

Barnaby, Ralph S., Ensign, U. S. Navy, Inspection Division of Naval Flying Corps.

Benson, Carl N., Machinist, Second Class, U. S. Navy, assigned to U. S. S. *Montclair*.

Buckingham, J. E. E., First Lieutenant, Engineers Corps, U. S. Army, assigned to Co. 7, Engineer Officers' Training School, Camp Humphreys, Va.

Bunker, W. D., Captain, Engineers' Corps, U. S. Army.

Chance, T. M., Major, Chemical Warfare Section, U. S. Army, assigned to Edgewood Arsenal, Md.

Clark, Albert J., Main Ship Cr 21, Naval Aviation Detachment, Cambridge, Mass.

Coldwell, C. B., Second Lieutenant, Ordnance Department, U. S. Army.

Cottman, Lewis W., Major, Gas Defense Division Chemical Warfare Service, U. S. Army.

Dagavarian, Nishan A., Chief Machinist's Mate, U. S. Steam Engineering School, U. S. Navy; assigned to Stevens Institute, Hoboken, N. J.

Danforth, T. Dwight, Second Lieutenant, Field Artillery, U. S. Army.

Demorest, William J., Captain, Ordnance Department, U. S. Army.

Everett, Chester M., Captain, Sanitary Corps, U. S. Army, Fort Oglethorpe, Ga.

Fell, Hugh P., First Lieutenant, Company D, Second Battalion, 37th Engineers, American Expeditionary Forces, France.

Fogler, B. B., Major, Mechanical Research and Development Section, Chemical Warfare Service, U. S. Army, assigned to Washington, D. C.

Fuller, Ray W., Major, Ordnance Department, U. S. Army.

Geddis, Robert H., Corporal, 16th Company, 152d Depot Brigade, Camp Upton, N. Y.

Goalwin, Harry A., Enlisted Medical Corps, U. S. Army.

Hanson, J. J., First Lieutenant, Inspection Division, Ordnance Department, U. S. Army, assigned to Minneapolis Steel & Machinery Co., Minneapolis, Minn.

Hill, George F., Captain, Ordnance Department, Chemical Warfare Section, U. S. Army.

Jackson, F. Raymond, Chief Machinist's Mate, U. S. Navy, Candidate Steam Engineers' School for Officers, Stevens Institute of Technology, Hoboken, N. J.

Judson, Cyrus F., Captain, Ordnance Department U. S. Army, assigned to Camp Logan, Houston, Tex.

Karmazin, John, Captain, Military Intelligence Division, General Staff, U. S. Army.

Kiefer, Paul J., Ensign, U. S. Navy, U. S. Navy Steam Engineering School, Hoboken, N. J.

Lacy, Robert, First Lieutenant, Company I, Engineer Officers' Training School, Camp Humphreys, Va.

Leh, C. F., Candidate, Engineer Officers' Training Camp, Camp Humphreys, Va.

Lincoln, C. W., Private, Co. E, 3d Regiment Air Service Mechanics' School, St. Paul, Minn.

Lockett, Kenneth, Captain, Engineers, U. S. Army.

Lucke, Charles E., Lieutenant-Commander, U. S. Navy.

Lundgren, Edwin, Coast Artillery, U. S. Army, assigned to Fort Monroe, Va.

Lundquist, Joseph M., Private, U. S. Infantry, assigned to Camp McArthur, Tex.

McArdell, Wesley, Private, Ordnance Student Officer Training School, Erie Proving Grounds, Port Clinton, O.

McIntosh, Samuel F., Captain, Ordnance Department, U. S. Army.

McMurtry, Alden L., Major, War Plans Division, General Staff, U. S. Army.

Mitchell, George L., Private, Intelligence Section, American Expeditionary Forces, France.

Muir, Leonard S., Second Lieutenant, Air Service Aeronautics, U. S. Army, assigned to Wilbur Wright Field, Dayton, O.

Mullergren, Arthur L., Lieutenant, Quartermaster Department, U. S. Army, Camp Funston, Kan.

Munson, Charles C., First Lieutenant, Air Service, Aircraft Production, U. S. Army.

O'Rourke, F. W., Private, Enlisted Ordnance Corps, U. S. Army, assigned to Ordnance School of Explosives Manufacture, Columbia University, New York

Peacock, Howard G., Private, 3rd Chemical Battalion, U. S. Army, Edgewood Arsenal, Edgewood, Md.

Porter, L. L., Ensign, U. S. Navy.

Price, A. M., Captain, Ordnance Department, U. S. Army.

Roe, J. W., Major, Air Service, Aircraft Production, U. S. Army.

Shirley, Harvey J., Machinist's Mate, 2nd class, U. S. Navy; attached to Student Army Training Corps, Navy Section, Cincinnati, O.

Slaughter, W. B., Jr., Master Engineer, U. S. Army, Searchlight Depot, American Expeditionary Forces, France.

Smith, Cameron O., Major, Ordnance Department, U. S. Army; assigned to the New York District Ordnance Office.

Smith, Harry R., Candidate, 30th Trench Battery, Field Artillery Corps Officers' Training School, Camp Zachary Taylor, Ky.

Spofford, Harry H. R., Ensign, U. S. Navy; assigned to U. S.S. *Mercury*.

Stanton, R. B., Jr., First Lieutenant, Student, Company 5, Engineer Officers' Training School, Camp Humphreys, Va.

Stinson, Karl W., Second Lieutenant, School of Military Aeronautics, U. S. Army, assigned to Princeton University, N. J.

Stuber, A., First Lieutenant, Signal Corps, U. S. Army.

Thayer, Paul W., Private, Co. D, First Replacement Regiment Engineers, Washington Barracks, Washington, D. C.

Turnbull, M. J., First Lieutenant, Engineers' Corps, U. S. Army.

Walker, Charles A., Second Lieutenant, R. E., British Expeditionary Forces, France.

Whitcraft, Arthur, Captain, Ordnance Department, U. S. Army.

White, Edward F., Lieutenant, U. S. Navy.

Women's Auxiliary of the A. S. M. E.

The Women's Auxiliary of the Society, coöperating with the Council of Organizations for War Service, offers opportunities for service in the centers established by the Section on Aliens, listed below. The officers of the Auxiliary hope to interest an increasing number of women through the two thousand members residing in the Metropolitan District and further information may be secured from the chairman of the Auxiliary, Mrs. Charles Ethan Davis, 885 West End Avenue, New York, N. Y.; telephone Academy 3167.

In New York City: Arnold Toynbee House, 331 East Broadway; Music School Settlement, 55 East Third St.; Emanuel Brotherhood, 309 East Sixth St.; Public School No. 74, 220 East Sixty-third St.

In Brooklyn: Brownsville Library, Glenmore Ave. and Watkins St.; Brownsville Children's Library, Stone and Dumont Aves.; Bushwick Library, Bushwick Ave. and Seigel St.; De Kalb Library, Bushwick and De Kalb Aves.; East Library, Arlington Ave. and Warwick St.; Eastern Parkway Library, Eastern Parkway and Schenectady Ave.; Greenpoint Library, Norman Ave. and Leonard St.; Kings Highway Library, 1608 Kings Highway; Leonard Library, Devoe and Leonard Sts.; Ridgewood Library, 496 Knickerbocker Ave.; Saratoga Library, Hopkinson Ave. and Macon St.; South Library, Fourth Ave. and Fifty-first St.; Williamsburgh Library, Division and Marcy Aves.; Winthrop Library, North Henry St. and Engert Ave.

Assistants are also desired for other branches of the Council's work, such as War Camp Community Service centers, baby-saving campaigns, etc. Details may be obtained from Miss Bernays at the Council's headquarters, 18 West Thirty-fourth Street, New York, N. Y.; telephone Knickerbocker 365.

At the Engineer Officers' Training School

A member of the Society who is in touch with the requirements of the officers' training schools offers the following suggestions for prospective applicants:

To those of our membership who are contemplating applying for engineer officers' commissions, a few notes on their status while in training will be instructive.

The embyro officer receives from the Adjutant-General a telegram appointing him a commissioned soldier, whereupon he puts a snug-fitting uniform decorated with bars or oak leaves and castles, and proceeds to Camp A. A. Humphreys, Virginia, chest well puffed out.

After reporting at the E. O. T. S. headquarters he becomes rapidly disillusioned as to his importance, and finds before nightfall that so far as the camp is concerned he is just a buck private. For the first four weeks he will receive daily about seven hours' infantry drill instruction, which will include the manual of arms, pack drill, bayonet drill, tent pitching, guard, outpost and reconnaisance duties. The rest of the course will be occupied with military engineering, such as bridges, pontoons, trench and dugout building, demolitions, military law, field service regulations, administrations.

The student officer will then take his turn at acting as commander or other officer.

The important point which all students should grasp at once is this: Their ability as engineers is not questioned and it is taken for granted that they are really capable; but what the army needs is *soldiers*, and it is the duty of the commanding officer in charge of the training school, and his assistant instructors, to make the men into soldiers. This means discipline, knowledge of warfare and, in the case of officers, the ability and personality to be in command of men.

LIBRARY NOTES AND BOOK REVIEWS

REVIEWS of books of special importance to mechanical engineers by members of the Society and those particularly qualified, brief descriptive notes of accessions to the Library of the United Engineering Society, items of interest relating to the Library's activities, etc.

CONCRETE STONE MANUFACTURE. By Harvey Whipple. Concrete-Cement Age Publishing Co., Detroit, 1918. Cloth, 5 x 7 in., 318 pp., 82 illus., 104 pl. $1.50.

A textbook for manufacturers of factory-made concrete units, based on the practice of various successful enterprises. Discusses plant layout, operation, methods, materials, finishing, building regulations, tests, etc.

FRENCH-ENGLISH AND ENGLISH-FRENCH DICTIONARY OF AVIATION By Robert Morris Pierce. N. Y. Languages Publishing Co., New York, 1918. Paper, 4 x 7 in., 12 pp. $0.60.

A brief bilingual dictionary of words and phrases, with the pronunciation carefully indicated.

GUIDE TO THE USE OF UNITED STATES GOVERNMENT PUBLICATIONS. By Edith E. Clarke. The Boston Book Co., Boston, 1918 Cloth, 6 x 9 in., 308 pp. $2.50.

A guide to the history, use, cataloguing and classification of United States government publications. Written primarily for librarians and library workers, it is broad enough in scope to serve as a laboratory manual for all who use the government publications inside libraries and out. Contains four bibliographies dealing with different phases of the subject.

HANDBOOK OF MECHANICAL AND ELECTRICAL COST DATA. Giving Shipping Weights, Capacities, Outputs and Net Prices of Machines and Apparatus, and Detailed Costs of Installation, Maintenance, Depreciation and Operation, together with Many Principles and Data Relating to Engineering Economics. By Halbert P. Gilette and Richard T. Dana. First Edition. McGraw-Hill Book Co., Inc., New York, 1918. Flexible Cloth, 5 x 7 in., 1734 pp., illus. tables. $6.

This handbook is similar in method to the authors' two previous handbooks covering costs in the field of civil engineering and can be used to supplement them. It is almost entirely devoted to purely electrical and mechanical subjects. Chapters on general economic principles, depreciation, repairs and renewals are included.

CONDENSED CATALOGUES OF MECHANICAL EQUIPMENT. With Mechanical Equipment Directory. Standardization Work of the Society, List of Transactions Papers, and Engineering Data are included. Eighth annual volume, October 1918. N. Y., The American Society of Mechanical Engineers. Cloth, 6 x 9 in., 812 pp., illus.

This edition of Condensed Catalogues has been enlarged by approximately thirty per cent. Four hundred and fifteen firms are represented by publication of catalogue data constituting a gain of nearly 100 firms as compared with the 1917 volume. The general directory of mechanical equipment has also been expanded to include over 3700 firms, classified under more than 2700 topics, and the directory of consulting engineers has been enlarged and improved. A subject list of the papers that have appeared in the thirty-nine volumes of the Transactions of the Society is included, together with a selection of engineering data from the Journal of 1917 and a summary of the Society's work on engineering standards. The volume is designed to be a primary reference work for buyers and users of mechanical equipment, giving the engineers specific data to assist in the selection of suitable machinery for various purposes.

MODERN NAVIGATION BY SUMNER-ST. HILAIRE METHODS. The First Published Work Devoted Exclusively to the Elucidation of This Subject, Now So Generally Used in the U. S. Navy. By Frank Seymour Hastings. Appleton & Co., New York, 1918. Cloth, 4 x 6 in., 84 pp. $0.75.

Presents the methods used in the Navy in an elementary form. Contains the merchant-marine method, the Sumner method and the Marcq St. Hilaire method. Intended as a supplement to the authors' Navigation—A Short Course.

PERSONALS

IN these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by November 15 in order to appear in the December issue.

CHANGES OF POSITION

RALPH E. CARPENTER has assumed the duties of director of service with the Aluminum Castings Company, Cleveland, O. He was formerly associated with The Taft Peirce Manufacturing Company, Woonsocket, R. I., in the capacity of sales manager.

WILLIAM T. WATERS, formerly connected with the Illinois Central Railroad, Chicago, Ill., as mechanical inspector, has become associated with Kehm Brothers Company, Chicago, Ill., and is now in charge of their contract for power and process piping at the U. S. Nitrate Plant, No. 3, Toledo, O.

ROBERT L. CLEGG has been appointed New England editor of *The Iron Age*. He was, until recently, vice-president of the Gardner Printing Company, Cleveland, O.

DAVID A. CHAPMAN, formerly vice president of the Dangel Company and the Touraine Company of Boston, is now with the U. S. Shipping Board as supervising engineer in charge of the training of chief engineers for turbine-driven ships, with headquarters at 173 Milk Street, Boston, Mass.

LOUIS J. SECKELS of the United Filters Corporation, San Francisco, Cal., has accepted the position of assistant engineer with the Oregon Short Line Railroad Company, Salt Lake City, Utah.

E. N. BATES, JR., assistant professor of mechanical engineering, Pennsylvania State College, State College, Pa., has become associated with the office of Grain Standardization, Bureau of Markets, Washington, D. C.

CLIFFORD LEE, formerly mechanical engineer, India Rubber Company, New Brunswick, N. J., has become affiliated with the Hercules Powder Company, Nitro, West Va.

FRANK C. SPENCER, until recently efficiency engineer, Western Electric Company, Chicago, Ill., is now connected with The Colt Patent Fire Arms Company, Hartford, Conn., in the capacity of superintendent of the Browning Gun Department.

STANWOOD W. SPARROW has left the employ of the Robert T. Pollock Company, Boston, Mass., to become associate engineer at the Bureau of Standards, Washington, D. C., in charge of the work in the altitude laboratory.

W. VAN ALAN CLARK, until recently engineer of plants, Tuco Products Corporation, Chicago, Ill., has entered the employ of the U. S. Shipping Board, Emergency Fleet Corporation, Philadelphia, Pa.

WILLIAM H. GRIFFITHS, leading designer, Department 29, Pratt and Whitney Company, Hartford, Conn., has accepted a position with the Remington Arms Union Metallic Cartridge Company, Bridgeport, Conn.

R. RENTON HIND has become affiliated with the Pacific Commercial Company, Manila, P. I. He was formerly connected with the Honolulu

Iron Works Company, Honolulu, Hawaii, in the capacity of consulting sugar-house engineer.

Albert Whatmore has been appointed chief engineer, Erith Oil Works, Ltd., Erith, Kent, England. He was formerly chief assistant engineer, The Olympia Oil and Coke Company, Ltd., Selby, York, England.

Vincent C. George, formerly instructor, Pennsylvania State College, State College, Pa., has been associated with the Engineering Extension Division, University of Wisconsin, Madison, Wis.

William L. Doten, formerly mechanical engineer with The Lamson Company, Boston, Mass., has assumed similar duties with the Sturtevant Mill Company,, Dorchester, Mass.

J. W. Brussel, until recently supervisor of machining at the Dayton Engineering and Laboratories Company, has accepted the position of superintendent with the Wright-Martin Aircraft Corporation, Long Island City, N. Y.

Edwin F. Church, Jr., formerly professor of machine design, West Virginia University, Morgantown, W. Va., has assumed the duties of professor of mechanical engineering, Brooklyn Polytechnic Institute, Brooklyn, N. Y.

Ira B. Dole, until recently connected with the Federal Creosoting Company, Bound Brook, N. J., in the capacity of agent, has become affiliated with the American Creosoting Company, of Hugo, Okla.

William Mulheron, until recently associated with Westinghouse, Church, Kerr and Company, New York, has become connected with the Chester Shipbuilding Company, Ltd., Philadelphia, Pa.

Roy B. Fehr has resigned his position as assistant professor of mechanical engineering at Pennsylvania State College, State College, Pa., to become assistant physicist for the Recording and Computing Machine Company, Dayton, Ohio.

M. R. Walton, formerly works manager of the Pennsylvania Salt Manufacturing Company, Natrona, Pa., is now employed as mechanical engineer with the Firestone Steel Products Company, Akron, Ohio.

George M. Keenan has become identified with the Lehigh Navigation Electric Company, Allentown, Pa. He was formerly connected with the Little Rock Railway and Electric Company, Little Rock, Ark., in the capacity of chief engineer.

C. A. Holdbridge, formerly factory manager of the Metalwood Manufacturing Company, of Detroit, Mich., has assumed the duties of mechanical superintendent of the Chalkis Manufacturing Company, Detroit, Mich., who are making 3-in. anti-aircraft guns for the United States Government.

Charles L. Frederick, formerly vice-president and general manager of the Passaic Metal Ware Company, Passaic, N. J., has assumed the duties of general manager of the Thurlow Steel Works, Chester, Pa. Mr. Frederick has recently had his Christian name changed, by order of the court, from Karl to Charles.

Andrew Westwater has resigned his position as chief engineer of the G. M. Standifer Construction Company, Vancouver, Wash., and has opened an office at Seattle, Wash., as consulting marine engineer and naval architect. Mr. Westwater has been appointed consulting marine engineer and Pacific Coast Representative of the General Ordnance Company, Denver, Colo., which is now using its shops for building marine engines and auxiliary machinery for marine service.

Frank H. Crockard, late president of the Nova Scotia Steel and Coal Company, and formerly vice-president and general manager of the Tennessee Company, has returned to Birmingham district as president of the Woodward Iron Company.

John J. Chisholm has started on his duties as superintendent of power for the Woodward Iron Company. He was formerly superintendent of power of New Orleans Railway and Light Company, New Orleans, La.

ANNOUNCEMENTS

In the 1918 Year Book the address and business connection of A. L. Roberts (1909), should have been listed as follows: Designing Engineer, Bethlehem Steel Company, Bethlehem, Pa., and for mail, 17 N. Centre Street, Bethlehem, Pa.

Howard M. Gassman will act as associate chief fuel conservator for the State of Alabama.

Edward G. Jay, Jr., has accepted the position of hull fittings engineer with the American International Shipbuilding Corporation, Hog Island, Pa. Mr. Jay will, however, still maintain his consulting engineering office in Philadelphia, Pa.

Arthur H. Morse has accepted the position of supervisor of technical training in the War Education Department of the University of Cincinnati, Cincinnati, O.

John Calder, who for a year after returning from France was engaged in organized seaplane production on a quantity basis at Keyport, N. J., has resigned as vice-president and general manager of the Aeromarine Plane and Motor Company of that city, and has assumed his consulting practice in industrial reports, organization and management at 35 West 39th Street, New York. Mr. Calder is also actively identified with the development of an all-steel airplane and has recently been elected vice-president of the Boyd Motors Corporation, controlling it.

Victor J. Azbe has terminated his connections with the Anheuser Busch Brewing Association, and has opened a consulting engineering office at 2194 Railway Exchange Building, St. Louis, Mo. His work will be in the direction of general power-plant efficiency.

Leon B. Jones, assistant engineer of the gas department of the Pacific Gas and Electric Company, San Francisco, Cal., has enlisted as a private of engineers in the United States Army. Mr. Jones has devoted much time and thought recently to the extraction of toluol from manufactured gas, and has been active in assisting the gas defense service of the United States Army.

Miss Kate Gleason has assumed the presidency of the First National Bank of East Rochester in the absence of H. C. Eyer, former president, who has left for Europe to engage in Y. M. C. A. work. Miss Gleason is probably the first woman to become president of a national bank of issue.

Edgar Buckingham, of the Bureau of Standards, has been appointed physical associate to the scientific attaché to the American embassy at Rome.

APPOINTMENTS

W. J. Armstrong, manager of the crushing and pulverizing sales department of the Jeffrey Manufacturing Company, Columbus, O., has recently received an appointment as Captain in the U. S. Army, and has been assigned to the Ordnance Department in Washington, D. C.

Herbert B. Reynolds, formerly mechanical assistant to superintendent of motive power of the United Railways and Electric Company, Baltimore, Md., has been appointed fuel engineer, U. S. Bureau of Mines.

Charles E. Waddell, of Asheville, has been appointed chief of conservation for North Carolina.

EMPLOYMENT BULLETIN

***The Secretary** considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.*

GOVERNMENT POSITIONS

Stamps should be inclosed for transmittal of applications to advertisers; non-members should accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

PRODUCTION, PLANNING AND SCHEDULING ENGINEERS to act as assistant shop superintendents in the Hull Division. Salary to start $6 per day. Location, New York. G0513-K.

ORDNANCE DEPARTMENT desires men as Directors of Training Departments to develop intensive training of workers in their factories at Philadelphia. G0667-K.

CHIEF INSPECTORS having considerable shop experience on steel and forging work and on machining of steel and trench warfare material. Positions will pay from $2500 to $3000 per annum, but men of considerably high calibre than seems commensurate with these salaries are asked to assist in this work. Location, Cincinnati District Ordnance Office. G0672-K.

SHOP INSPECTORS ON BARBETTE CARRIAGES are desired by Maryland Plant. Position requires engineer having had experience in the assembly of heavy machinery, in gathering and consolidating complete data from the rough forging or casting to finished carriage, also data of shop maneuvering tests before shipment. Salary $2400 per annum. G0673-K.

CONSTRUCTION DIVISION desires men as City Managers and assistant to officer in charge of Military Camps of 40,000 men. Men must possess initiative to meet all emergencies of maintenance and repair, and ability to command working force of 400 to 950 men. Prefer men over 40 years of age with administrative experience in operation of public utility properties. Although the salary is not commensurate with ability, the need for responsible men is urgent. G0681-K.

INSPECTORS AND PRODUCTION ENGINEERS. Large engineering concern requires the services of several men to inspect and expedite the production of electrical and mechanical apparatus on Government and essential work. Reply quickly, stating age, education, brief outline of experience, salary expected and when available. Location, New York City. G0687-K.

ENGINEERS from 30 to 35 years of age having general manufacturing experience on mechanical work desired by plant in West

Virginia. Position temporary, about 3 months, with possibility of becoming permanent. Salary $200-$250 per month. G0690-K.

UNITED STATES RAILROAD ADMINISTRATION desires draftsmen on power-plant design. Salary $120-$175 per month. Location, New York City. G0691-K.

DETAIL DRAFTSMEN AND DESIGNERS. Munitions Plant in Brooklyn desire services of two men. Salary to start $30 per week. G0695-K.

ORDNANCE DEPARTMENT desires two experienced mechanical engineers for experiment and development work on munitions and fuses. Salary $250 to $350 per month. G0702-K.

DRAFTSMEN. The Navy Department is desirous of obtaining the services of draftsmen Salary commensurate with ability. Location, Washington. G0717-K.

ASSISTANTS in important research work in the fatigue of metals, especially as applying to war problems, such as aircrafts, crank shafts and electric welding of ships. Investigations to be carried on at own laboratory or at laboratory in Middle West. G0719-K.

DESIGNERS AND DRAFTSMEN for experiment station. Positions would exempt from draft. Salaries for designers up to $185 a month; for draftsmen up to $115. Location, Connecticut. G0739-K.

FOREST SERVICE. Engineers and assistant engineers are desired. Salary for engineers from $1800 to $3000; assistant engineers from $1500 to $1800. Location, Middle West. G0744-K.

HULL DRAFTSMEN. Those having experience in wooden hulls preferred. Location, New York. G0747-K.

NAVAL GUN FACTORY needs technical graduates who are competent designers of jigs, tools and gages. Salary $4 to $6.88 per day. Location, Washington. G0748-K.

MECHANICAL AND SAFETY ENGINEER having two or more years' practical shop experience. Must be tactful and able to confer with high executives and Government officials. Excellent opportunity to make wide acquaintance in engineering profession. Salary $1800 to $2500. Apply by letter. Name will not be given in this record. G0767-K.

CIVILIAN POSITIONS

BIG OPPORTUNITY in an old-established business for practical man who can offer a few specialties for manufacture, one with combination of mechanical and executive ability understanding sheet-metal and light-screw machine work and who can develop sheet-metal specialties that can be marketed to afford volume production to the factory. Location, New York. K-0460.

ELECTRICAL ENGINEERS on plans and specifications. Some drafting. Americans wanted. Salary $1200, $1400 or higher if necessary. Location, New York Central. K-0718.

SALES ENGINEERS in various district offices. Air compressor manufacturer. State qualifications, experience if any, and compensation expected. K-0216.

MECHANICAL ENGINEER. Excellent opportunity for technical man with shop and drafting-room experience with growing concern in Connecticut making high-grade specialized product. Work interesting and carries considerable responsibility. Give full particulars. K-0257.

ASSISTANT TEST ENGINEER, technical graduate not subject to draft, with experience in steel heat-treatment and testing work for growing concern in Connecticut making high-grade specialized product; knowledge of chemistry an advantage. Good opportunity and work interesting. Give full particulars in answering. K-0258.

INSTRUCTOR IN MECHANICAL ENGINEERING to teach descriptive geometry, machine drawing, some laboratory work, and elementary steam engineering. Salary $1800 per year. Location, Ohio. K-0433.

MECHANICAL ENGINEER with experience in design, testing, and general engineering work in connection with small and medium steam turbines. Must have good business and executive ability, reduction-gear experience also desirable and be able to handle variety of work in connection with steam turbines and turbine-driven machines. Give full details of training, experience and salary expected. Photograph desirable. Location, Connecticut. K-0464.

MECHANICAL ENGINEER with machine-shop experience for position similar to master mechanic. Salary, $50 to start. Location, Brooklyn. K-0468.

PROFESSOR OF MECHANICAL ENGINEERING in charge of department, technical graduate with both teaching and practical experience. Give full statement of training and experience, references and late photograph. Salary $240 per month for next ten months. Location, Idaho. K-0471.

MECHANICAL ENGINEER AND DESIGNER with extensive experience in the design and construction of shipbuilding cranes, derricks, drag-line excavators and similar work. High-grade man wanted to take charge. Location, Pennsylvania. K-0475.

DRAFTSMAN, high-grade man with experience on boiler design. Salary $175 to $225. Location, Pennsylvania. K-0482.

DRAFTSMAN, high-grade man with experience on locomotive-crane design. Salary $175 to $225. Location, Pennsylvania. K-0483.

DRAFTSMAN, high-grade man with experience on the design of steel towboats and barges. Salary $175 to $225. Location, Pennsylvania. K-0484.

SEVERAL FIRST-CLASS DRAFTSMEN with broad engineering experience. Good future for right men. Location, Ohio. K-0496.

THREE ENGINEERS, experienced in substituting mechanical equipment for hand labor. Must be familiar with all kinds of conveying equipment. Good future for right men. Location, Ohio. K-0497.

ASSISTANT MECHANICAL ENGINEER familiar with general machinery in machine shop and mill engineering; must be competent to lay out and direct installation of new machinery and direct repairs and alterations on present equipment. Concern manufacturing mechanical rubber goods and employs about 2000. Technical graduate preferred. Salary $1500 to $2000, depending on man. Location, Massachusetts. K-0498.

MECHANICAL ENGINEERS AND DRAFTSMEN for designing machinery wanted by large and long-established company, located near New York City. K-0502.

TURBINE DESIGNER, experienced, capable of taking complete charge of design and construction of turbines and reduction gears, wanted by large and long-established company, located near New York City. K-0503.

DRAFTSMEN AND DESIGNERS, experienced in calculating automatic machinery, typewriters, etc. Permanent positions offered to competent men. Location, New York City. Salary about $35 per week. K-0512.

MECHANICAL ENGINEER, five years' experience or better for gas and fuel company. Salary $175 to start. Location, Colorado. K-0669.

DRAFTSMEN AND TRACERS, electrical and mechanical engineers for plant layout work. K-0670.

CHECKER on patterns and drawings. Prefer man with textile-machinery experience, although not absolutely essential, if experienced with other lines of machines. Location, Boston. K-0671.

MECHANICAL ENGINEER to supervise completion and later maintenance of Government plant on power side, requiring some construction experience, heat, light, sanitary distribution of power and electrical engineering. Splendid opportunity for right man. Location, New Jersey. K-0675.

DRAFTSMAN on power building and power-plant piping. Salary depends on man. K-0676.

DRAFTSMAN on layout of crushing and ore plant. Transmission work, elevators and conveyors. Salary depends on man. K-0677.

DRAFTSMEN familiar with foundation plans, arranging of machinery and shop equipment in connection with large extension to plant. Rate approximately $1.00 per hour. Time and a half for overtime beyond eight hours. Location, Camden, New Jersey. K-0678.

POWER-HOUSE ENGINEER to study operating conditions, repair and execute plans and methods for increasing economy, in power house of 6,000 kw. generating capacity, serving an essential industry. Excellent opportunity for advancement to position of assistant chief engineer for man with executive ability. State full details of education and experience, age, draft status and salary expected. Location, Detroit. K-0683.

MECHANICAL ENGINEER in connection with construction and maintenance department of large manufacturing plant executing only Government orders. Applicant must be competent to study and design heating and steam-distribution problems, air-conveyor systems, installation of motors, line shafting and conveyor for handling materials. Technical education desirable but not necessary. Give full details of education and experience, age, nationality, draft standing and salary expected. K-0684.

ASSISTANT ESTIMATOR on minor buildings, alterations, rearrangements and items of equipment in large manufacturing plant executing war orders. Ability to make free-hand sketches necessary but skill as a draftsman or technical education unnecessary. Position affords opportunity for advancement in construction and maintenance department. State experience, age, nationality and draft status. Information confidential. Location, Detroit. K-0685.

CHIEF DRAFTSMAN capable of taking charge of drawing room employing three or four men, in designing equipment, minor buildings and rearrangements in large manufacturing plant, engaged exclusively in war work. Technical education or expert skill as designer unnecessary. Must be thoroughly practical and experienced in factory arrangement and operation. State education, experience in detail, age, draft standing and salary expected. Information confidential. Location, Detroit. K-0686.

EFFICIENCY ENGINEERS with at least one year's experience; preferably college men, mechanical, electrical or civil engineering training. Salary $125 to $175 with yearly bonus amounting to 60 up to 90 per cent of year's salary, depending on earnings of company. Location, New York. K-0688.

JUNIOR ENGINEERS, three, willing to learn efficiency engineering; preferably college men, mechanical electrical or civil engineering training. Salary $100 to $125 per month with yearly bonus amounting to 60 up to 90 per cent of year's salary, depending on earnings of company. Traveling involved. Draft exempt. Location, New York. K-0689.

WORKS MANAGER for plant located in New Jersey manufacturing several lines of specialties, must have broad general business experience and good judgment and be familiar with modern duplicate parts manufacture. Preferably technical graduate who has worked with up-to-date productions, central controlling and planning system.

Man capable of earning $6,000 to $7,000. Position will develop to general manager and possible opportunity for acquiring substantial interest in company, if services are satisfactory. Location, New York. K-0693.

COMBUSTION ENGINEER who will go to the bottom of things and give some logical solution of power-plant troubles in paper mills. Young progressive man or older man beyond the draft age; some drafting, designing, etc. Good opportunity. Liberal salary, depends generally on the ability of man. Location, Middletown, Ohio. K-0696.

YOUNG MECHANICAL ENGINEER as assistant to consulting engineer for a large nationally-known manufacturing concern. Must be technical graduate and in deferred classification under selective service act. Experience in heating and power-plant engineering desirable. Work is directly connected with the war work; position permanent with excellent opportunities for advancement. Location, New York City. Outline experience and state salary expected. K-0699.

METALLURGIST. Preferably with smelting experience in copper or lead, either civil or mechanical. Salary from $3500 to $5000. Headquarters, New York. K-0700.

DRAFTSMEN in shipbuilding line. Location, Staten Island. K-0701.

MECHANICAL DRAFTSMEN, 10 on industrial plant layout. Salary $30 to $50 per week. Location, New York. K-0704.

INDUSTRIAL DRAFTSMEN, three; salary $30 to $50 per week. Location, New York. K-0705.

TRACERS, three, about $30 per week. Headquarters, New York City. K-0706.

MACHINE SHOP FOREMAN, competent to supervise lathes, milling, boring, and screw-machine hands. Salary $2800 per year. Location, Philadelphia. Apply by letter. K-0709.

INSTRUCTOR for steam engineering. Location, Seattle, Washington. K-0710.

HIGH-CLASS MECHANICAL ENGINEER having both the training and experience which will fit him to act in the capacity of chief engineer to master mechanic of plant, capable of taking care of the mechanical power and refrigerating engineering connected with a packing house. If qualified to have charge of all the construction work as well as the engineering end. Location, Ohio. K-0711.

COMBUSTION ENGINEER for large industrial plant in South operating 12,000 hp. steam plant; state technical training, practical experience and salary earned and expected, together with copies of references. K-0712.

MECHANICAL DRAFTSMAN (women with necessary qualifications will be accepted) with some experience in building construction. Experience in furnace-combustion work preferred. Permanent position. State age, experience and salary expected. Location, New York City. K-0714.

CHIEF ENGINEER capable of handling new 16,000 kw. turbine-driven steam-power generating station. Position is with public service corporation. Requires man who can take complete charge of the plant, looking after its economical operation and maintenance. No duties other than operation of plant. Location, Philadelphia. K-0716.

ELECTRICAL ENGINEERS on plans and specifications. Some work on drafting board. Americans wanted. Salary $1200, $1400 or higher if necessary. Headquarters, New York City. K-0718.

TWO MECHANICAL DRAFTSMEN with piping experience. Salary as high as $60 per week, depends on man. Location, Wilmington, Del. K-0720.

FOUR MECHANICAL DRAFTSMEN with industrial-plant experience. Salary as high as $60 per week, depends on man. Location, Wilmington, Del. K-0721.

TWO MEN with reinforced concrete experience. Salary as high as $60 per week, depends on man. Location, Wilmington, Del. K-0722.

FOUR MEN, structural-steel designers. Salary as high as $60 per week, depends on man. Location, Wilmington, Del. K-0723.

SEVERAL MEN to inspect and expedite the production of electrical and mechanical apparatus on government and essential work for large engineering concern in New York City. Apply quickly, stating age, education, brief outline of experience, salary expected and when available. K-0724.

SALES ENGINEER, technically-educated man, preferably between ages of thirty and forty, with successful experience in sales problems in metal-manufacturing industries. Liberal salary and interesting, patriotic work for one with right qualifications, which must include a vigorous personality and ready command of written English. In reply, state age, college or technical school, date and degree, whether married or single, specify chronologically account of business experience, present and expected salary. Location, Boston, Mass. K-0725.

COMPETENT BOILER INSPECTOR, to be employed by Hawaiian Sugar Planters' Association, for inspection of boilers of sugar mills and pumping plants, locomotives, etc., on members' plantations. Must understand boiler-insurance companies' requirements. State training, experience, references, and salary expected. K-0726.

EMPLOYMENT DIRECTOR for a small machine shop building engines for Government work. Location, Western Pennsylvania. Man thoroughly competent to get men, keep them, and arrange for the training of unskilled labor to enable it to do skilled machinist's work. Permanent position and good salary. New York concern. K-0727.

APPRAISERS for number of manufacturing properties. Salaries would depend on qualifications of applicants. Philadelphia concern. K-0728.

ELECTRICAL AND MECHANICAL ENGINEER. Under civil service law. Position will pay about $3,300 per year at the start and $3,600 as soon as incumbent has fully demonstrated ability to satisfactorily handle work. Includes operation, maintenance and repair of electric lighting system for boulevards and parks, including high-tension transformer sub-stations, and transmission lines, and all auxiliary apparatus; also design, maintenance and repair of illuminating equipment in all park buildings. Preparation of plans and specifications for alterations and new electrical construction work and supervision of their execution will also be included. Location, Illinois. K-0729.

APPRAISER on general machinery, machine shop and all mechanical machinery. Salary $1500 to $3000. Headquarters, New York City. K-0730.

SUPERINTENDENT for metal-stamping plant in Alexandria, Indiana. Man should be experienced in both metal-stamping and screw-machine work, also die and tool making. About 200 men employed in plant devoting 95 per cent of its production to war orders. K-0731

PRODUCTION MANAGER who is able to deserve by his ability and experience, a salary of $9,000 or $10,000 per year. Needs to be a good production manager in the fullest sense of the word. K-0732.

DESIGNING ENGINEER in charge of drafting and design work in connection with the application of roller bearings to all kinds of industrial apparatus. Age 26 to 40. Thoroughly familiar in machine shop and drafting room on heavy machinery design. Location, New York City. Salary $2000. K-0733.

SUPERINTENDENT OR PRODUCTION MANAGER. Quality of handling men and system of more importance than mechanical ability. Location, Connecticut. K-0743.

CHIEF OPERATING ENGINEER to have charge of the power plant, 9000 hp., 3250-kw. capacity, an additional steam plant for heating and industrial purposes of about 400 hp., large hydraulic pump room giving power for benches, rams, etc., and several other centres of steam-using apparatus. Salary about $3000 a year. Location, near New York. K-0745.

GENERAL FOREMAN in plant department to have charge of from 150 to 200 men, made up of electricians, plumbers, steamfitters, carpenters, painters, laborers, etc., who would be responsible for the maintenance and construction work in a plant employing about 3000 hands. Position about $3000 a year. Plant is running between 90 and 100 per cent for the government, mostly on direct orders for the Army and Navy. Location, near New York City. K-0746.

ENGINEERS to train and develop in the fundamentals of firm primarily engaged in the distillation of coal tar with resultant principal production of bituminous road and roofing materials, with the ultimate object of filling operating positions in various plants as foreman, head chemist, assistant superintendents, or superintendents. Preferably men of chemical engineering training, but not essential. As contemplated work will eventually be of an executive nature, ability to handle men is a desirable asset. Location, New York. K-0749.

SALESMAN for special class of machinery. Man with technical training and ability to meet the engineering staffs of large organizations. Location, Ohio. K-0750.

DESIGNERS on tools, jigs and fixtures. Salary $40 a week. Location, Brooklyn, New York. K-0751.

DRAFTSMEN experienced in construction and repair of machinery for industrial plants, qualified to design special machinery and making layouts of new equipment. Prefer men with chemical-plant experience or who have done drafting for consulting engineer. Permanent position in an essential industry with 40 per cent of plant devoted to government work. State qualifications and details of past experience. Salary $1400 to $1600 to start. K-0752.

ELECTRICAL ENGINEER principally for shop inspection and to superintend the erection of electric monorail and traveling-crane equipment, with incidental miscellaneous office and field work. Man in class 2D, 3 or 4 of the draft. K-0753.

DRAFTSMAN to do all-around work connected with engineering department. Metallurgical and chemical concern. Location, New York. K-0754.

ASSISTANT EMPLOYMENT MANAGER, man with some mechanical training. Appointment can be made through New York office. Location, Connecticut. K-0288.

DRAFTSMEN for Connecticut plant. Men of recognized ability desired. Appointment can be made through New York Office. K-0289.

TIME-STUDY WORK, men of ability. Location Connecticut. K-0290.

YOUNG ENGINEER over draft age, single, to go to head office in Chile, S. A., of company operating several plants in nitrate district. Should have some experience in industrial cost analysis and efficiency work, in addition to general engineering experience. Salary $3000 a year to start. K-0316.

DRAFTSMAN for proposition department. Design of power-house and boiler-rooms and making estimates of costs, as an aid to sales department. Believe opportunities for young men of ability are exceptional. Location, New Jersey. K-0207.

FIRE PROTECTION ENGINEER. Large plant in Detroit requires man to guard

against fire hazards. Should be fully informed as to modern fire-prevention methods, with sufficient training and education in electricity and chemistry to fully appreciate hazards of this sort. In applying, state age, draft status, nationality, extent of education, detailed experience, present employment, etc. K-0247.

CONTROLLING INTEREST in prosperous machine tool and gage manufacturing concern to be sold for best offer. Present owner to enter service. Well known firm of wide reputation. Location, Connecticut. K-0259.

CAPABLE PRACTICAL MAN to take entire business control of machine shop building special machinery, gages and tools. Engineer with business knowledge and experience in this line of work preferred; interest in the business may be acquired by the right man. Location, Connecticut. K-0260.

SALESMAN familiar with sale, design and making of special machinery, tools, gages and fixtures; practical mechanical experience necessary. Good opening for right man. Location, Connecticut. K-0261.

ENGINEERS, college graduates, men out at least a year, for general shop engineering work with growing concern. Work leads to industrial management. State full particulars. Location, New Jersey. K-0265-E.

EXPERIENCED COPY WRITER to handle building construction and equipment accounts. Exceptional opportunity with New England agency for man who knows the contracting field and can show satisfactory evidence of ability through copy and catalogue matter already written. K-0267.

MECHANICAL DRAFTSMEN with technical education, experienced on vacuum-heating systems and high-pressure steam piping. Location, New York. K-0329.

DRAFTSMEN with experience in conveying machinery and general engineering. Salary, $175 to $200. Location, New Jersey. K-0336.

TOOL MAKERS OR MACHINISTS. Location, Newark, New Jersey. K-0341.

DRAFTSMEN, some experience in chemical plants. Location, New York City. K-0346.

MECHANICAL DRAFTSMEN experienced in power-transmission and machinery-arrangement work. Work in question will probably be over two months' duration and good salaries will be paid competent men. Traveling expenses from New York to West Virginia and return, and living quarters furnished without charge. K-0347.

MECHANICAL DRAFTSMEN in electrical department of large railroad company. Men familiar with large power-station work. Immediate work in hand is installation of a 20,000 kw. turbo-generator with the necessary condensing apparatus, boilers, stokers, coal and ash handling apparatus, etc. Salary, $174 per month. Location, New York. K-0352.

MACHINE DESIGNERS on fixtures, jigs, etc., flat salary of $25 and opportunities at high rates by the hour. Location, Connecticut. K-0353.

SALES ENGINEER, energetic and willing to work. Must be thinker with engineering college degree, one year shop work on machine design, or a high-school education with two or three years shop work on machine design. Between 25 and 32, draft exempt, or class 4. Salary $1500 to $1800. Location, New York as headquarters to travel. K-0355.

DRAFTSMEN on power-house layout and piping. Salary depends on man. Location, New York. K-0382.

DRAFTSMAN on marine-engine work in factory having large Government contract. Permanent employment for the right party. One having oil engine experience preferred. Location, New York State. K-0384.

SHIPBUILDING DRAFTSMEN. Salary, $35 to $40. Location, Brooklyn, N. Y. K-0386.

TURBINE MAINTENANCE ENGINEER. Man for inspection of turbine and auxiliary equipment and taking care of the major repairs to apparatus, for large power company operating several stations. Location, Pennsylvania. K-0412.

BOILER MAINTENANCE ENGINEER. Man for inspection of boiler and boiler-room apparatus. One with construction experience in large boilers preferred. Location, Pennsylvania. K-0413.

SUPERINTENDENT for growing concern having machine shop, foundry, pattern and blacksmith shop just starting on attractive specialty, requires capable superintendent experienced in above lines, and a good systematizer. Excellent opportunity for young man. Location, Michigan. K-0417.

SALES ENGINEER having thorough technical and practical knowledge in electrical work, telephone equipment and installation and equipment of electrical apparatus in general, to travel Pacific Coast for New York corporation. Man between 25 and 35, having good personality and appearance coupled with selling ability, preferably in class 4A of draft. Knowledge of shipbuilding industry is desirable. Traveling expenses paid. Salary, drawing account plus commission. K-0692.

EXPERIENCED COKE OVEN OPERATOR and supervising gas-works engineer in city near Atlantic seaboard, where residence conditions are agreeable and excellent schooling and college education available for children. Write, giving in detail experience and technical education, references, expected salary and how soon available. Applications will be considered confidential. An excellent permanent position for the right man. K-0742.

HIGH-CLASS MAN who has combined engineering and selling ability. Location, Buffalo, New York. K-0755.

ASSISTANT ENGINEER with technical training and experience in construction and repairs of industrial plants, qualified to design special machinery and capable of making layouts of new equipment so as to obtain efficient utilization of floor space and economical plant operation. Permanent position. Prefer man with experience in chemical plant or office of consulting engineer. State qualifications and details of past experience. Salary, $1500 to $2000, according to ability. Location, Southern Ohio. K-0756.

MECHANICAL DRAFTSMAN in engineering department in our New York office. Pay $150 to $175 per month for man capable of doing detail work and light designing. Location, New York. K-0757.

NEW YORK FIRM OF INDUSTRIAL AND SCIENTIFIC MANAGEMENT ENGINEERS desires to take into their engineer staff with purpose of training, men who are draft exempt for work classified as "essential" by a number of District Boards and by the Provost General's office. Splendid training is given in production increasing and management work in large variety of industries, together with opportunity for managerial position. K-0758.

DRAFTSMAN experienced in mill and power piping, all classes of heating. Man over 36 years of age or else with dependents. Location, Massachusetts. K-0760.

SALES ENGINEER, prominent pumping machinery concern desires to add four men to its sales organization, to sell centrifugal pumps and steam turbines. Only men who know machinery, who are versed in the pump and turbine atmosphere, and who are fully conversant with the engineering problems involved in erection and operation of centrifugal pumps and steam turbines will be considered. Liberal salary plus commission on each sale and choice of four sales territories, namely New York, Philadelphia, Detroit, or Boston, is offered. Location, New York. Apply by letter. Name confidential. K-0761.

ELECTRICAL AND MECHANICAL ENGINEER. Position will pay about $3300 per year at the start and $3600 per year as soon as the incumbent has fully demonstrated his ability to satisfactorily handle the work. Under civil service law. Work includes operation, maintenance and repair of electric lighting system for boulevards and parks, including high-tension transformer sub-stations, and transmission lines, and all auxiliary apparatus; also the design, maintenance and repair of illuminating equipment in all park buildings. Preparation of plans and specifications for alterations and new electrical construction work and supervision of their execution will also be included. Location, Illinois. K-0729.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be on hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

MEMBER, mechanical engineer, technical education, 12 years' experience plant layout, structural steel, timber construction, conveying, elevating, power-transmission machinery. Now in sole charge work involving expenditure $200,000 designing, purchasing materials, directing field work. Minimum salary $350 month. K-261.

TECHNICAL GRADUATE with 10 years' experience in steam and hydraulic power-plant design and construction work, desires position with concern engaged in essential business, also plant-operation and plant-machinery installation work. K-262.

EXECUTIVE ENGINEER, M. I. T. graduate, Member. 20 years' experience along mechanical electrical lines, and in organizing and purchasing. American; location preferred, New York City or vicinity. K-263.

CHIEF DRAFTSMAN OR PRODUCTION ENGINEER, 10 years' experience as draftsman, designing, motors, jigs, tools, plant layout, furnaces, charge of machine-shop production, efficiency, at present on consulting work; position desired in New York City, Newark, or vicinity. Salary $180 to $200 per month. Married, three dependents, American, 33 years of age. K-264.

DESIGNING AND MAINTENANCE ENGINEER. Mechanical engineer, University of Pennsylvania graduate, desires connection as designing engineer or chief draftsman with concern where merits would be appreciated. Past experience includes design, erection and maintenance of large industrial and power-plant installations in supervising capacity. At present engaged as designing engineer. K-265.

PRODUCTION ENGINEER, competent in plant and production equipment, open for engagement preferably in metropolitan district. K-266.

WORKS MANAGER OR ASSISTANT. Graduate of Purdue University, degree of M.E.; 18 years' experience in freight-car work. Experienced in heavy presses, steel and hydraulic presses. Designer of dies for heavy pressing. Familiar with tank-car construction and maintenance. Location, middle west preferred, but other location considered if the inducements are there. Married, over 36, probably draft exempt. K-267.

MECHANICAL ENGINEER desires executive position offering greater opportunities than present position as works engineer for large company. Member, age 38, married. Technical graduate, practical experience in carpentry, plumbing and machine shop. Drafting experience in mining machinery, power pumps and electrical machinery. Engineering experience covers power-plant work, both generation and distribution. Repair and maintenance, new construction and industrial work in general, especially equipment for pattern, wood, box-making and machine shops, iron and brass foundries, grinding, polishing, buffing, hardening, japanning, coslittizing, electro-plating and other special processes. In charge of work relative to compensation and labor laws,

welfare, safety, watchmen's and firemen's organization, public relations. Can handle big propositions and large numbers of men successfully. K-268.

SALES ENGINEER having business-getting record is open for engagement as manager of sales, in charge of responsible district office or on a basis in line with experience and qualifications. Can give satisfactory evidence of ability and character. Change is contemplated because of present conditions curtailing activities. K-269.

TOOL SUPERINTENDENT, ASSISTANT CHIEF ENGINEER, CHIEF DRAFTSMAN. Progressive, energetic engineer, desires to make connections with manufacturing concern needing an engineer with training and broad experience as well as ability to produce results. Excellent references, open for engagement about December 1. K-270.

PRODUCTION OR PRODUCTION EQUIPMENT ENGINEER, or other responsible position, designing or manufacturing end or both. Must be war work. Salary about $4000. Would like to correspond with party needing self-starting man. Practical mechanic and designer. Experience covers originating, designing, building and operating numerous special and standard automatic and semi-automatic machines for producing wide variety of articles from wire, sheet metals, paper, wood, etc., for assembling labor saving, processing, conveying, cost reducing, etc. Punches and dies, jigs, fixtures and tools and general engineering, routing, cost accounting, bookkeeping, time study and production. 28 years old, married with family, draft exempted. Will go anywhere. K-271.

INDUSTRIAL AND SALES ENGINEER possessing ability to supervise plant manufacturing iron and steel products, specializing in power-house equipment. Trained mechanical engineer, experienced in purchasing, designing, manufacturing and sales promotion. Able to take entire charge of business and successfully market product, desires permanent executive position to start about $6000 and advance rapidly as results are shown. American, 40, married, with family, very successful record and large earning capacity. K-272.

INDUSTRIAL ENGINEER, designer, complete experience from shop apprentice to sales agency, technical graduate, 43 years of age, married, faultless record, will go anywhere, especially coast district in south. K-273.

MECHANICAL ENGINEER, age 24, wishes position preferably in Middle West. K-274.

MECHANICAL ENGINEER, now chief engineer of an industrial car company, desires position with manufacturing company, as mechanical engineer, or other executive position. Ten years' experience in general mechanical engineering. Thoroughly conversant with technical and practical side of standard railway and industrial equipment. Competent to assume full charge and to produce results. Salary not less than $3600. K-275.

FOUNDRY SUPERINTENDENT OR MANAGER, thoroughly practical, iron, brass, and composition foundry man, having wide experience on all classes of iron and brass castings. Over draft age; satisfactory references furnished, also satisfactory reason for wishing to make change from present position. K-276.

TECHNICAL EXECUTIVE with broad American and foreign experience desires position abroad, preferably in reconstruction work in France or England. American-born, college graduate, associate member, age 31, Class 4. Experience as engineer and executive in production, design, tool-work, organization, and management. Well-balanced, resourceful, dependable. Salary $8000 to $10,000. K-277.

POWER-PLANT EXECUTIVE. Technical graduate, age 31, Class 4 of draft, with 10 years' experience in power-plant construction, reconstruction, operation and management, desires position of this nature more directly connected with war work. At present employed. Salary considered $3600 to $4000. K-278.

MECHANICAL ENGINEER Member, age 45, married, technical graduate. 20 years' experience, covering design, construction, operation of cement plants. Thoroughly conversant with boilers, engines, turbines, motors; at present superintendent of large plant, wants to change for larger responsibilities; will go anywhere, available any time. K-279

PRODUCTION ENGINEER. Thorough experience in planning, dispatching, cost system. Analytical, creative ability and tact rated the highest. Age 32, 4th class draft. Salary $5000. K-280.

TECHNICAL GRADUATE with over ten years' experience in design, construction, operation and maintenance of manufacturing and power equipment is desirous of making new connection as mechanical engineer or in other executive capacity in line with his qualifications. Capable and conscientious worker with the best of references. Minimum salary $3600. K-281.

EXECUTIVE, 38, desires connection where mechanical training, including 18 years in design, development, manufacture, sale and installation of boiler room equipment would be of service; traveled extensively, familiar with fuel problems, excellent correspondent, hard worker. Chicago preferred K-282.

INDUSTRIAL OR PUBLIC UTILITY EXECUTIVE, member, technical graduate, age 46, American, Protestant. Unusual combination of general business, financial and engineering experience. Thoroughly grounded in mechanical and electrical engineering, including design, construction, operation, examinations, appraisals, utilities and industrial undertakings. Especially successful in organizing and directing large working forces for construction and operation in different sections of the country where local conditions and labor problems differ greatly. A profit-sharing arrangement with a small enterprise that has a future or salary commensurate with ability. K-283.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER NOVEMBER 21

BELOW is a list of candidates who have filed applications since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of applications 164.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by November 21, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

DEMPSTER, William J., Fuel Agent, Montgomery Light & Traction Co., Birmingham
JONES, George W., Draftsman, Republic Iron & Steel Co., Birmingham

California

AUSTIN, Henry W., Senior Mechanical Engineer, Interstate Commerce Commission, San Francisco
KINGWELL, William A., Owner, Brass Foundry & Machine Works, San Francisco
LLOYD, Bruce, Manager, Engineering Dept., Henry Lund & Co., San Francisco

HEATH, LEWIS W., Treasurer, General Manager, Consolidated Press Co., Hastings

LEWIS, JOHN G., Vice-President & Factory Manager, Detroit, Screw Works, Detroit

MORRISSEY, JOHN M., Field Superintendent & Service Engineer, Diamond Power Specialty Co., Detroit

New Jersey

KOPF, EMIL A., Assistant to Mechanical Engineer, Singer Mfg. Co., Elizabeth

MEEKS, HOWARD V., Treasurer, The Gardner & Meeks Co., Union

MURPHY, TIMOTHY J., Field Engineer, American Steel & Wire Co., Trenton

WATTS, GEORGE A., JR., Salesman, General Utility Man, Watts Campbell Co., Newark

New York

BERNDT, IRVING A., Vice-President, C. E. Knoeppel & Co., Inc., New York

BORSUK, ANTON, General Superintendent, Presto Machine Works, Brooklyn

CHAMBERLAIN, REGENALD P., Tool Designer, Pierce Arrow Motor Co., Buffalo

COFFEY, BARTON H., Chief Engineer, Cooling Tower Co., Inc., New York

EDWARDS, HARRY D., Chief Draftsman, The Linde Air Products Co., New York

EVANS, LEIGH R., Vice-President & Factory Manager, Cyclemotor Corp., Rochester

FEILD, WILLIAM T., Construction & Maintenance Engineer, American Car & Fdry. Co., Depew

FLIFLET, THORLEIF, Chief Engineer, Walter Kidde & Co., Inc., New York

FREE, ALBERT V., Assistant to Principal in Charge of Academic Work, Saunders Trades School, Yonkers

GRIMMER, FREDERIC H., Machine Shop Superintendent, Cameron Machine Co., Brooklyn

HOPF, HARRY A., Consulting Industrial Engineer, New York

KELLER, M. W., Manager, Engineering & Research Dept., Oneida Community, Ltd., Kenwood

KNAPP, ARTHUR, President, Arthor Knapp Engineering Corp., New York

LOFTIN, ALEXANDER J., Assistant to Superintendent, Fidelity & Casualty Co. of New York, New York

McCULLOUGH, CHARLES H., JR., Vice-President & General Manager, Lackawanna Steel Co., Buffalo

MANVILLE, KEITH R., Designer, Curtiss Engineering Corp., Long Island City

NEUBAUER, GEORGE A., Mechanical Engineer, The Buffalo Pitts Co., Buffalo

PACKARD, ROLAND A., Superintendent of Power, Barnet Leather Co., Little Falls

SEARLE, ERNEST M., Mechanical Engineer, Standard Oil Co. of New York, Albany

SHAFFER, MATTHEW T., Mechanical Engineer, The Barrett Co., New York

THOMAS, EDWARD H., Chief Inspector of Chemical Plant Construction, Ordnance Dept., U. S. A., New York

VAN GORDER, WINFRED H., Superintendent, C. J. Tagliabue Mfg. Co., Brooklyn

VUILLEUMIER, RUDOLPH, Chief Engineer, Pintsch Compressing Co., New York

WHITAKER, HARRY E., Engineer, Ford, Bacon and Davis, New York

North Carolina

MAULDIN, EARLE, Engineer of Construction, R. J. Reynolds Tobacco Co., Winston-Salem

MEISTER, CONRAD L., Mechanical Engineer, A. C. L. R. R., Wilmington

Ohio

ANDERSON, HAROLD, N., President, Anderson Rolled Gear Co., Lakewood

CASE, ALLANDO A., Instructor, Machine Shop Practice, Ohio State University, Columbus

DRAKE, WILLIAM A., Secretary and Sales Manager, The Brownell Co., Dayton

GARDNER, ROLLAND, Commercial Engineer, Westinghouse Elec. & Mfg. Co., Cleveland

JONES, SIDNEY W., Inspector, New Construction, Youngstown Sheet & Tube Co., Youngstown

KEYS, WALTER C., Acting Director of Engineering, The Standard Parts Co., Cleveland

KNECHT, ARTHUR E., Production Engineer, National Cash Register Co., Cincinnati

MORRIS, GEORGE M., President & Treasurer, The Morris Machine Tool Co., Cincinnati

PILLIOD, CHARLES J., Designer, The Pilliod Co., Swanton

SHIELDS, FRANK S., President, The Cleveland Planer Co., Cleveland

Pennsylvania

AUSTIN, WALTER M., Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh

BROSIUS, EDGAR E., Contracting Engineer, Pittsburgh

CUNNINGHAM, OTTO H., Charge of all fuel and power conservation work, Allegheny Steel Co., Breckenridge

FULLER, JOHN T., Mining Engineer, Aluminum Co. of America, Pittsburgh

HUGHES, HARRISON H., Master Mechanic, Carnegie Steel Co., By-Product Coke Wks., Clairton

KLINE, CHAS. W., Draftsman, New Jersey Zinc Co., Palmerton

MERRITT, JAMES S., Philadelphia Manager, The Engineer Co., New York Philadelphia

SCHRANZ, CHARLES A., Manager, Hydraulic Machinery Dept., R. D. Wood & Co., Philadelphia

SLOAT, BENJAMIN C., Div. Superintendent of Hull Construction, American International Shipbuilding Corp., Hog Island

SULLENBERGER, JOHN K., Construction Engineer, Bethlehem Steel Co., Bethlehem

WRIGHT, RAYMOND D. B., Sales Engineer, Harrison Safety Boiler Woorks, Philadelphia

ZINK, JOHN H., Construction Engineer, Bethlehem Steel Co., So. Bethlehem

Texas

BASTION, J. A., Construction Engineer, The Texas Co., Port Arthur

WILSON, CHESTER W., Consulting Engineer, American Smelting & Refining Co., El Paso

Virginia

TOPHAM, WILLIAM O., Superintendent Engineer and Engineer, Surveyor Shipping Control Committee, Newport News

WEIDMAN, WILLIAM R., Captain Engineers, 517th Service Battalion, Camp A. A. Humphreys

Washington

BOUSCHOR, WILLIAM E., Puget Sound Manager, Williamette Iron & Steel Wks., Seattle

FLODIN, JOHN, Draftsman, C. M. Standifer Construction Corp., Vancouver

MATHESON, W. SCOTT, Vice-President and Manager, Westerman Iron Wks., Seattle

West Virginia

STEVENSON, CHARLES M., Works Engineer, Rollin Chemical Co., So. Charleston

Wisconsin

NAGLER, FORREST, Sales Engineer, Allis-Chalmers Mfg. Co., Milwaukee

Canada

WOOD, REGINALD H., Lieutenant, Chief Engineer, Esquimalt Naval Dockyard, Esquimalt, B. C.

England

JOHNSON, LAWRENCE W., Consulting Engineer & Technical Director, Messrs. Banks, Warner & Co., Ltd., London

France

PIERCE, PAUL L., Lt. Col., Ordnance Dept., U. S. N. A., American Expeditionary Forces

Mexico

TAYLOR, WILLIAM R., Chief Mechanical Engineer, Mexican Eagle Oil Co., Minatitlan

South America

McINTYRE, OTIS L., Mechanical Superintendent, Cerro de Pasco Copper Corp., La Fundicion, Peru

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

Arizona

BUCHEN, JOSEPH C., Mechanical Engineer, Miami Copper Co., Miami

California

CARTER, THOS. F., Mechanical Engineer, Western Pipe & Steel Co., Los Angeles

New York

INGLEE, CLINTON, Treasurer & General Manager, National Water Main Clearing Co., New York

LAPP, ROY B., Plant Engineer, Ingersoll Rand Co., Painted Post

PAVITT, WILLIAM H., Assistant Chief Engineer, Wilputte Coke Oven Corp., New York

Ohio

SCHUTTLER, CARL H., Assistant District Supply Manager, U. S. Shipping Board Emergency Fleet Corp., Youngstown

Pennsylvania

FLETCHER, HOWARD J., Production Manager, Miller Lock Co., Frankford

Washington

MAGUIRE, WALTER J., Chief Inspector, Pacific Coast Steel Co., Seattle

SEIM, OLIVER P., Dispatcher, Navy Yard Puget Sound, Bremerton

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

California

HOUGHTON, HARRY S., Construction Engineer, C. F. Braun & Co., San Francisco

Connecticut

HUMASON, LAWRENCE C., Secretary & Treasurer, The Peck & Young Mfg. Co., Forestville

MERRY, ARTHUR A., Assistant Works Manager, Pratt & Whitney Co., Hartford

MILLINGER, William A. F., Assistant Engineer, American Can Co., Bridgeport

District of Columbia

ABRAMS, Lawrence B., Engineer, Ingersoll-Rand Co., Washington
MAIER, Dwight C., Aeronautical Mechanical Engineer, Bureau of Aircraft Production, War Dept., Washington

Illinois

FISCHER, Franz W., General Superintendent, The Liquid Carbonic Co., Chicago

Massachusetts

GEORGE, Harry A., Chief Cost Accountant, The Heald Mch. Co., Worcester

Michigan

BAITS, Stuart G., Engineer, Hudson Motor Car Co., Detroit

New Jersey

MULLER, Joseph, Mechanical Designer, Crocker-Wheeler Co., Ampere
REITZEL, Jacob H., Rate-Setter, Crocker-Wheeler Co., Ampere

New York

BAUMEISTER, Paul A., Mechanical Engineer, Ingersoll-Rand Co., New York
LAHRS, Louis J. T., Director of Physical Education, Y. M. C. A., Buffalo
LEINROTH, Jean P., Foreman of Welding Dept., Bossert Corp., Utica
MARTIN, Walter H., Small Tool Engineer, Arthur Knapp Engineering Corp., New York
NEWBY, Clarence L., Engineer, Hyatt Roller Bearing Co., New York
PIPEROUX, Rene P., Chief Estimating Engineer, Honolulu Iron Wks., New York
STEELE, Francis J., Jr., Assistant Chief Draftsman, Naval Auxiliary Reserve, New York
WILLIAMS, Harry H., Safety Engineer, Wynkoop Service, New York

Ohio

FELLOWS, John A., Assistant Superintendent, Machine Dept., American Rolling Mill Co., Middletown
STOESSER, Leo P., Production Engineer, The American Rolling Mill Co., Hamilton
WHITMAN, Ray B., Assistant to Chief Inspector, U. S. Shipping Board, Emergency Fleet Corp., Cleveland

Pennsylvania

KLEIN, Stephen L., Superintendent, Lykens Valley Fuel Co., Williamstown
SHEPHEARD, George R., Assistant Chief Engineer, The Viscose Co., Marcus Hook

Wisconsin

FRASER, John, Jr., General Manager, The Fraser Co., Milwaukee

Canada

McKINNON, R. A., Factory Manager, McKinnon Industries, Ltd., St. Catherines

Hawaii

SEMPLE, David M., Works Manager, Catton Neill & Co., Ltd., Honolulu

FOR CONSIDERATION AS JUNIOR

California

COBERLY, Clarence J., Engineer, California Burdett Oxygen Co., Los Angeles

Connecticut

NELSON, Ralph M., Assistant Mechanical Engineer, Ashcraft Mfg. Co., Bridgeport

Delaware

GROW, Harold J., Assistant Foreman, Welding Dept., Bethlehem Shipbuilding Corp., Wilmington

District of Columbia

OLIVER, Herman G., Experimental Engineer, Science & Research Div., U. S. A., Washington

Georgia

McGOWN, Clark Y., Ordnance Dept., U. S. A., Camp Hancock

Indiana

STILZ, Oscar W., In Charge of Production Dept., Nordyke & Marmon Co., Indianapolis

Maryland

HINE, Russell C., Steam Engineer, Consolidated Gas, Electric Light & Power Co., Baltimore

Massachusetts

BLUE, Edward W., Scovell, Wellington & Co., Boston

Missouri

SIROKY, Edmond, Instructor in Mechanical Engineering, Washington University, St. Louis

New Jersey

CHANDLER, Sherman M., Assistant Engineer, Standard Aero Corp. of New York, Plainfield
EDWARDS, William W., Millwright, Dusenberg Motors Corp., Elizabeth

New York

ANDERSEN, Andreas H., Manager, A. Hermansen, New York Branch, New York
CETRULE, John, Chief Inspector, Blair Tool & Mch. Wks., Inc., New York
DOXSEY, Arthur M., Assistant Engineer of Tests, Hull Division, Navy Yard, New York
HAUSEL, Walter M., Assistant to Chief Draftsman, Otis Elevator Co., Yonkers
HYDE, George G., Assistant Engineer of Design & Construction, Eastern Potash Corp., New York

Ohio

WHITE, Thomas H., Assistant to Vice-President, White Motor Co., Cleveland
WUEST, Frank W., Assistant in Planning and Time-Study Dept., The Lodge & Shipley Mach. Tool Co., Cincinnati

Oregon

FERRELL, Fred C., General Foreman, Spokane, Portland & Seattle Ry., Portland

Pennsylvania

BRITTON, Howard, Jr., Representative, Brass Goods Dept., Manning, Maxwell & Moore, Inc., Pittsburgh
NICHOLAS, John E., Shop Engineer, Bethlehem Steel Co., Bethlehem
RABE, Frederick W., Condenser Test Floor Engineer, Westinghouse Elec. & Mfg. Co., Wilkinsburg
TEFFEAU, Louis M., Mechanical Draftsman, A. I. S. B. Co., Philadelphia

France

LEISTER, Fayette, Master Engineer, 103rd Engineers, U. S. A., American Expeditionary Forces
PAULES, Parvin E., Lieutenant, Aviation Section

CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

Michigan

STANBROUGH, Duncan G., General Superintendent, Packard Motor Car Co., Detroit

New York

PRICE, Melvin, Assistant Professor of Machine Design, University of Rochester, Rochester

PROMOTION FROM ASSOCIATE-MEMBER

Missouri

RUPP, Manning E., Superintendent, Shell Forging Plants, Curtis & Co. Mfg. Co., St. Louis

New Jersey

KING, Frank A., Construction Engineer, Wright-Martin Aircraft Corp., New Brunswick

New York

HAMPSON, Donald A., Mechanical Executive, Morgans & Wilcox Mfg. Co., Middletown
OBERG, Erike V., Editor, "Machinery," New York

PROMOTION FROM JUNIOR

District of Columbia

FOGLER, Ben B., Major, Mechanical Research, Chemical Warfare Service, Washington

Massachusetts

HERRICK, Daniel A., General Superintendent, Julian d'Este Co., Boston

Mississippi

SHARP, John T., Superintendent, Canton Elec. Light & Water Wks., Canton

New Jersey

MOON, Alfred G., Maintenance Engineer, Hercules Powder Co., Kenvil

New York

LINKER, Abraham, Designer on Industrial Plant, Perin & Marshall, New York
McMILLAN, Luther B., Consulting Engineer, H. W. Johns-Manville Co., New York
MANDEL, Arthur C., Engineering Dispatcher, Wright-Martin Aircraft Corp., Long Island City
OSBOURN, Millard P., Chief Engineer, Badenhausen Co. (Reinstatement), New York
REBER, James B., Superintendent, Columbian Rope Co., Auburn
VAN DERVORT, Adrian O., Superintendent, Hammett Machine Works, Troy

Pennsylvania

PRIEBE, Ernest B., Chief Draftsman, Stoker Eng. Dept., West. Elec. & Mfg. Co., E. Pittsburgh

SUMMARY

New Applications	164
Applications for change of grading:	
Promotion from Associate	2
Promotion from Associate-Member	4
Promotion from Junior	11
Total	181

SUMMARY SHOWING AVERAGE AGE AND POSITIONS OF APPLICANTS ON BALLOT OCTOBER 24, 1918

Average age of applicants:	
Members	39
Associates	38
Associate-Members	32
Juniors	25
Aeronautical Mechanical Engineer	1
Associate Editor	1
Chief Engineer	2
Assistant Chief Engineer	1
Consulting Engineer	2
Designers	3
Draftsmen	2
Chief Draftsmen	3
Executives (Pres., Vice-Pres., Secy., Treas., Mgrs.)	20
Foreman	1
Inspector	1
Assistant Inspector	1
Instructor	1
Master Mechanic	1
Mechanical Engineers	14
Assistant Mechanical Engineers	2
Motor Engineer	1
Operating Engineer	1
Plant Engineer	1
Production Officer	1
Professor	1
Resident Engineer	1
Sales Engineer	1
Superintendents	5
Assistant Superintendent	4
Miscellaneous	17

UNITED STATES GOVERNMENT SERVICE

Major	1
1st Lieuts	2

SELECTED TITLES OF ENGINEERING ARTICLES

THE section Selected Titles of Engineering Articles comprises an index to current articles on mechanical engineering and related subjects.

This work has been made possible by the remarkable collection of current technical periodicals available in the Library of the United Engineering Society, which is one of the greatest and most complete collections in the world. The Library receives, even now, when some of the foreign periodicals have ceased to come to its shelves, close to a thousand different papers, magazines and transactions of societies in the engineering and scientific fields, in not less than ten languages. The Society's engineering staff examines these publications as they are received and prepares the cards which are ultimately used in the Selected Titles section of THE JOURNAL.

Chief attention is paid to articles directly concerned with the branches of mechanical engineering. When it is thought they will be of interest or value to mechanical engineers, however, other articles are listed, in the realms of physics and chemistry; civil, mining and electrical engineering, technology, etc.; and in subjects in broadly related fields such as training and education, safety engineering, fire protection, employment of labor, welfare work, housing, cost keeping, patent law, public relations, etc. Cross-references are introduced and where the titles themselves are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC PRINTS

Photostatic copies may be obtained of any of the articles listed in this section.

Price of each print (up to 11 x 14 in. in size), 25 cents, plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Orders should be sent to

HARRISON W. CRAVER, *Director,*
Engineering Societies Library,
29 West Thirty-ninth Street,
New York.

AERONAUTICS

Aerostatics

Military Aerostatics, H. K. Black. Aerial Age, vol. 7, nos. 24, 25, 26, Aug. 26, Sept. 2, Sept. 9, 1918, p. 1167, 1 fig., p. 1219, p. 1267, 1 fig., vol. 8, nos. 2 and 3, Sept. 23 and Sept. 30, 1918, p. 65, 1 fig., p. 119, 1 fig. Aug. 26: Science of ballooning; Cocquot type, Model *M*, operated by Royal Flying Corps. Sept. 2: Parachute harnesses. Sept. 9: Dimensions of American observation balloons. Sept. 23: Construction of balloon winches. Sept. 30: Handling a balloon in the field.

Altitude

An Alignment Chart for Obtaining Heights from Observations of Pressure and Temperature, A. H. Stuart. Aerial Age, vol. 7, no. 26, Sept. 9, 1918, p. 1275. Constructed by solving Laplace's equation between height above datum level and pressure and temperature of atmosphere, by means of a d'Ocagne alignment chart.

Problems in Flying at High Altitudes, W. Kasperowicz (Translated from French by Augustus Post). Flying, vol. 7, no. 8, Sept. 1918, pp. 714-715. Changes produced by reduced air pressure.

Bolts

On the Strength of Bolts in Airplane Structure, John Case. Aeronautics, vol. 15, no. 252, Aug. 14, 1918, pp. 134-139, 17 figs. Formulæ and rules for design; strength of bolts, in spars and the like, when subject to transverse loads at the ends; distribution of loads between bolts holding single plate under tension; distribution of load between bolts of joint subjected to bending. (To be continued.)

Enemy Aircraft Exhibit

The London Enemy Aircraft Exhibit. The Fokker Biplane, G. Douglas Wardrop. Aerial Age, vol. 8, nos. 2 and 3, Sept. 23 and 30, 1918, pp. 68 and 87, 1 fig. and p. 130, 1 fig. Sept. 23: Data of design of captured German machine of D VII type. Sept. 30: Halberstadt two-seater.

Engines

Aluminum Pistons for German Airplane Engines, C. Vickers. Brass World, vol. 14, no. 9, Sept. 1918, pp. 258, 1 fig. Drawing and description of aluminum piston taken from a 230-hp. Benz motor of captured Aviatik biplane.

Enemy Aircraft Engines (VIII). Automobile Engr., vol. 8, no. 116, July 1918, pp. 194-199, 11 figs. 180-hp. Mercedes: cylinders and other parts; lubrication; ignition; water-circulation system; power and consumption curves.

Modern Aeronautic Engines (II), Herbert Chase. Jl. Soc. Automotive Engrs., vol. 3, no. 3, Sept. 1918, pp. 205-208, 17 figs. Details of Sunbeam and Rolls-Royce (English) and Hall-Scott (Am.) engines. (Concluded.)

The Design of Aeroplane Engines, John Wallace. Aeronautics, vol. 15, nos. 251 and 252, Aug. 7 and 14, 1918, pp. 116-118, 7 figs., and 141-143, 6 figs. Aug. 7: Remarks on two-cylinder engines; twin-cylinder Vee engine; horizontally opposed twin; three-cylinder; four-cylinder vertical. Aug. 14: Three-cylinder radial engines; five-cylinder radial. Determination of results. (Continuation of serial.)

The 240-H.P. 8-cylinder Mercedes. Aerial Age, vol. 7, nos. 25 and 26, Sept. 3 and 9, 1918, pp. 1220-1221, 4 figs., pp. 1270-1274, 17 figs. Sept. 3: Detailed report on design of a captured German two-seater; summary of tests; cylinders; reduction gear. Sept. 9: Crank chamber; vertical driving gear; lubrication; water circulation; water-pump test report; ignition; air pump; engine data; general analysis of weights of parts.

The 300-H.P. Maybach Aero-Engine. Engineering, vol. 106, no. 2748, Aug. 30, 1918, pp. 226-228, 17 figs. Detailed and illustrated description of the six-cylinder German engine. Also published in Engineer, vol. 126, no. 3270, Aug. 30, 1918, pp. 184-186, 7 figs. and in Flight, vol. 10, no. 36, Sept. 5, 1918, pp. 995-1000, 10 figs. Connecting rods; valve gear; cam diagram and valve timing; crankshaft. (Continuation of serial.)

Individual Types

A Fokker Biplane of Recent Type. Flight, vol. 10, no. 30, July 25, 1918, pp. 829-831, 1 fig. Details of a captured German machine.

Some New Enemy Airplanes. Aviation, vol. 5, no. 4, Sept. 15, 1918, pp. 235-237, 9 figs. Dimensions and nature of Albatros D. 5, and of Fokker D. 7. Summary from L'Aérophile, L'Aéroplane, Flight and Flying. (To be continued.)

The D.H. 5 Pursuit Biplane. Aviation, vol. 5, no. 4, Sept. 15, 1918, pp. 228-229, 7 figs. Description of an English tractor biplane with a single pair of interplane struts on either side and with wings set at a negative stagger of 0.695 m. Also published in Aerial Age, vol. 8, no. 2, Sept. 23, 1918, pp. 70-71, 6 figs. Translated from Zeitschrift für Flugtechnik und Motorluftschiffahrt.

The Hannoveraner Biplane. Flight, vol. 10, no. 36, Sept. 5, 1918, pp. 987-993, 28 figs. Details of construction of captured plane. Report of Technical Department, Aircraft Production, Ministry of Munitions.

The Pfalz Single Seater Fighter—160 H.P. Mercedes Engine. Flight, vol. 10, nos. 30, 31, 32, 33, July 25, Aug. 1, Aug. 8, Aug. 15, 1918, pp. 822-827, 5 figs., pp. 855-856, 3 figs., pp. 885-888, 7 figs., pp. 905-908, 5 figs. July 25: Official data; diagrams showing method of covering body with ply-wood; wing roots. Aug. 1: Mounting of the tail-plane root; details of runner. Aug. 8: Safety-belt attachment; control handle; undercarriage. Aug. 15: Wiring diagram; wing structure and arrangement. Also published in Automotive Ind., vol. 39, no. 10, Sept. 5, 1918, pp. 406-409, 7 figs.

Giant Zeppelin Airships (Les avions géants Zeppelin). L'Aérophile, year 26, nos. 15-16, Aug. 1-15, 1918, pp. 225-242, 33 figs. Plans and details of captured machine, 22 m. long, 41 m. wide. Also published in Aerial Age, vol. 8, no. 3, Sept. 30, 1918, pp. 122-125, 6 figs.

Materials of Construction

Tests of Materials Used in Aeroplane Construction (L'essai des matériaux servant à la construction des aéroplanes). Génie Civil, vol. 73, no. 10, Sept. 7, 1918, pp. 188-191, 13 figs. Machines used for verifying equilibrium of parts; details and operation of Avery elongation and rupture-testing machine; tests made on textile fabrics.

Meteorology

Some Meteorological Conditions Which Increase the Danger of Flying, C. J. P. Cave. Aerial Age, vol. 8, no. 2, Sept. 23, 1918, p. 64, 2 figs. Rain, hail and snow; lightning; fog. (Concluded.)

Model Aeroplanes

Model Aeronautical Building as a Step to Aeronautic Engineering. Aerial Age, vol. 7, nos. 23, 24, 25, 26, Aug. 19, Aug. 26, Sept. 2, Sept. 9, 1918, p. 1127, 1 fig., p. 1183, 1 fig., p. 1231, 16 figs., p. 1283, 1 fig., vol. 8, nos. 2 and 3, Sept. 23 and Sept. 30, 1918, p. 77, 3 figs., and p. 135, 10 figs. Aug. 19: Method of fastening and rigging main planes. Aug. 26: Construction of tail, rudder, fin and propeller. Sept. 2: Compressed-air motor. Sept. 9: Details of motor; tank construction. Sept. 23: Steam-engine construction. Sept. 30: Gasoline-engine principle and construction.

Ornithopter

The Ornithopter, Herbert Chatley. Aviation, vol. 5, no. 4, Sept. 15, 1918, p. 237. Possibilities and requirements of the real bird machine.

Propellers

Notes on Airscrew Analysis, M. A. S. Riach, Aerial Age, vol. 7, no. 24, Aug. 26, 1918, pp. 1173-1179, 3 figs. Analysis of changes likely to be brought about by variation in one or more of the parameters involved in hypothesis upon which is based the theory of airscrew previously outlined by writer.

U. S. Aircraft Production

Aircraft Production in the United States. Flying, vol. 7, no. 8, Sept. 1918, pp. 721-726, 738 and 744. Complete report of the Senate Subcommittee on Military Affairs.

See also Metallurgy (Aircraft); Physics (Air); Woodworking Machinery (Propeller-Shaping Machines).

AIR MACHINERY

Air Compressors

Lubrication of Air Compressors, W. H. Callan. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 575-577. Shows that most oil experts figure on heat conditions which do not exist and recommend the wrong oil.

NOTE. The abbreviations used in indexing are as follows: Academy (Acad.); And (&); American (Am.); Associated (Assoc.); Association (Assn.); Bulletin (Bul.); Bureau (Bur.); Canadian (Can.); Chemical or Chemistry (Chem.); Electrical or Electric (Elec.); Electrician (Elecn.); Engineer [s] (Engr. [s]); Engineering (Eng.); Gazette (Gaz.); General (Gen.); Geological (Geol.); Heating (Heat.); Industrial (Indus.); Institute (Inst.); Institution (Instn.); International (Int.); Journal (Jl.); London (Lond.); Machinery (Machy.); Machinist (Mach.); Magazine (Mag.); Marine (Mar.); Materials (Matls.); Mechanical (Mech.); Mining (Min.); Municipal (Mun.); National (Nat.); New England (N. E.); New York (N. Y.); Record (Rec.); Refrigerating or Refrigeration (Refrig.); Review (Rev.); Railway (Ry.); Scientific or Science (Sci.); Society (Soc.); United States (U. S.); Ventilating (Vent.); Western (West.); State names (Ill., Minn., etc.); Proceedings (Proc.); Transactions (Trans.); Supplement (Supp.).

Persberg Installation of Hydraulic Air Compressors (Hydraulisk luftkompressoranläggning vid Persberg), Gust. Anderson. Biuang till Jern-Kontorets Annaler, vol. 19, no. 7, July 15, 1918, pp. 271-296, 23 figs.

Blowers

Installation and Care of Sturtevant V D-5 Turbo-Blower, F. W. Sterling. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 480-489, 5 figs. Operating rules; enumeration of parts; emergency governor mechanism; packing; bearings; lubrication.

Test of Sturtevant Forced Draft Blower, M. C. Stuart. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 453-479, 19 figs. Performance at various speeds, steam pressures and back pressures of non-condensing vertical turbine with cone-type fan mounted on shaft directly above turbine; performance of fan at various speeds and capacities; performance of combined unit.

Compressed-Air Applications

Uses of Compressed Air in the Modern Shop, P. C. Frank. Can. Machy., vol. 20, no. 11, Sept. 12, 1918, pp. 309-313, 20 figs. Considerations on amount of clearance, cooling of air in cylinders and action of valve, in reference to efficient operation.

Flow of Air

The Flow of Air Through Small Coal and Other Broken Material: Report to the Doncaster Coal Owners' Committee, John T. Storrow. Trans. Instn. Min. Engrs., vol. 55, part 4, Aug.-Sept. 1918, pp. 313-317, 1 fig. and (discussion) pp. 317-323. Experiments to ascertain under what conditions the rate of flow of air through a porous material varies directly as the ventilating pressure, and not with the square root of it, as in the case in ordinary pipes.

BIBLIOGRAPHY

See Lubrication (Viscosity); Safety Engineering (Dust Inhalation); Varia (Automobile Insurance).

BRIDGES

Bridge Reconstruction

Strengthening Poughkeepsie Bridge Superstructure. Ry. Age, vol. 65, no. 11, Sept. 13, 1918, pp. 473-476, 9 figs. Engineering features of efforts to increase capacity by changing from double track to single gauntlet track accommodations.

Reinforced-Concrete Bridges

A New Type of Iron-Concrete Arch, M. Frontard. Eng. & Cement World, vol. 13, no. 4, Aug. 15, 1918, p. 37. Structure built by bridging gap with rails bent to curvature of arch and finishing with concrete.

The Canadian Pacific Railway's Second Track Work Between Leaside Junction and North Toronto. Can. Ry. & Marine World, no. 247, Sept. 1918, pp. 378-380, 5 figs. Features of design of 386-ft. reinforced concrete bridge over reservoir ravine; structure supported on two abutments and five towers.

Steel Arch Bridges

The Economics of Steel Arch Bridges, Indian Eng., vol. 64, nos. 3 and 4, July 20 and 27, 1918, pp. 39-41 and 53-54. Formulæ for weights of metal in arches per linear foot of span, based on designing specifications. (Continuation of serial.)

BUILDING AND CONSTRUCTION

Camp Model Towns

Construction Camps Model Towns on Miami Flood Works. Eng. News-Rec., vol. 81, no. 13, Sept. 26, 1918, pp. 575-578, 8 figs. Details of plan of village and floor plans of houses; village comprises houses, schools, community halls, markets, water mains, lights and sewers.

Concrete Culverts

Standard Practice in Concrete Culvert Construction, H. Colin Campbell. Eng. & Cement World, vol. 13, no. 4, Aug. 15, 1918, pp. 19-20. Tables giving relation between area drained and area of waterway, and data on reinforced-concrete box culverts.

Foundations

Foundation Construction for New Station at Kansas City. Elec. Rev., vol. 73, no. 13, Sept. 28, 1918, pp. 492-493, 7 figs. Problems encountered in the work on 150,000-kw. plant on Missouri River.

House Construction

House Construction and Design. Contract Rec., vol. 32, no. 35, Aug. 28, 1918, pp. 677-679, 7 figs. Various types and sizes of concrete houses adopted for work of reconstruction of Halifax.

Mill Buildings

Reconstruction of Consumers' Cordage Plant at Dartmouth. Contract Rec., vol. 32, no. 35, Aug. 28, 1918, pp. 687-688, 4 figs. Description of repair and reconstruction of buildings severely damaged by Halifax explosion.

Office Building

The Office Building of the Department of the Interior, Charles Butler. Architectural Rec., vol. 44, no. 3, Sept. 1918, pp. 199-213, 17 figs. Plans and elevations.

Piles

Carrying Capacity for Various Types of Piles, H. W. Young. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, pp. 28-29. Strengths computed by Patton's formula for a 30-ft. pile under average soil conditions.

See also Power Plants (Vibration).

CEMENT AND CONCRETE

By-Products

Conserving the By-Products of the Cement Mills, W. G. Clark. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, pp. 61-62, 1 fig. Opportunities in increasing efficiency by recovery of potash dust.

Concrete Proportioning

Methods of Proportioning Concrete Based on Recent Experimental Work, D. A. Abrams, Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 206-207. Notes based on author's work at Lewis Institute.

Concrete, Shock-Resisting

A New Shock Resisting Concrete. Can. Machy., vol. 20, no. 9, Sept. 5, 1918, pp. 297-298. Proportions of ingredients in concrete composed of portland cement with particles of moss, turf, or wood (pulverized or pulped), and metallic ores, with a binding liquid consisting of a soluble salt of alumina, lime and water.

Deterioration

Causes of the Disintegration of Concrete, A. G. Blackie. Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 200-203. Comparison of theories advanced by Montana Experimental Station, Bul. 81, Feb. 1911, and by Bureau of Standards, Tech. Paper 95, 1917, with results of work developed at Univ. of Wyoming Experimental Station, Bul. 113, Mar. 1917; account of author's tests made by determining action of various alkali solutions upon sands used locally in composition of concrete.

Chemistry of Concrete, Arch. Blackie. Can. Engr., vol. 35, no. 10, Sept. 5, 1918, pp. 231-233. Former and present theories explaining the disintegration of concrete; rules for making tile; distintegrated sewers; alkali action on sands; Winnipeg water district tests. Paper before Sasketoon Section, Eng. Inst. of Can.

Observations of Concrete Failures, H. McD. Weir. Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 203-206. Report of investigating committee appointed by Calgary Branch, particularly in relation to alkali conditions.

Reinforced Concrete v. Salt, Brine, and Sea-Water, H. J. M. Creighton. Page's Eng. Weekly, vol. 33, no. 726, Aug. 9, 1918, pp. 66-67. Corrosion of iron reinforcement due to action of brine; probable reactions which occur when metal comes in contact with a salt solution. Paper before Faraday Soc. (To be continued.) Also published in Min. Jl., vol. 122, no. 4329, Aug. 10, 1918, pp. 473-475.

The Deterioration of Concrete Due to Alkali Conditions. Contract Rec., vol. 32, no. 37, Sept. 11, 1918, pp. 743-745. Causes of distintegration; tables of analysis of samples; conclusions. Report presented by Calgary Branch Committee before Eng. Inst. of Canada.

Oil and Concrete

Effect of Oil on Concrete, C. P. Bowie. Practical Engr., vol. 58, no. 1642, Aug. 15, 1918, pp. 79-80. Reports on experiments performed under auspices of So. Pac. RR. Abstracted from Oil Storage Tanks and Reservoirs, Bul. 155, Bureau of Mines, Washington.

Portland Cement

Government Specifications for Portland Cement. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, p. 17. Definition, chemical limits, specific gravity, fineness, soundness, time of setting, tensile strength, packages and marking, storage, inspection, rejection, and treatment of samples.

See also Bridges (Reinforced-Concrete Bridges); Building and Construction (Concrete Culverts); Roads and Pavements (Concrete Roads).

CHEMICAL TECHNOLOGY

Flames

Residual and Extinctive Atmospheres of Flames, T. F. Eric Rhead. Jl. Soc. Chem. Ind., vol. 37, no. 16, Aug. 31, 1918, pp. 274T-278T, 2 figs. Experimental determination of oxygen contents for flames of various gases, the inert gas employed for the extinctive atmosphere being nitrogen.

Gasoline

The Recovery of Gasoline from Natural Gas, W. P. Dykema. Petroleum Rev., vol. 39, no. 841, pp. 138-140. Considerations to be made before designing a compression plant to treat natural gas from a given area. (To be continued.)

High-Temperature Processes

High Temperature Processes and Products, Chas. R. Darling. Jl. Royal Soc. of Arts, vol. 66, no. 3432, Aug. 30, 1918, pp. 635-642, 8 figs. Thermit processes and application of thermit to welding of iron and steel; electric steel smelting; fixation of atmospheric nitrogen; formation of calcium carbide; carborundum and allied substances.

Natural Gas

The Chemical Possibilities of Natural Gas, J. B. Garner. Chem. Engr., vol. 26, no. 7, June 1918, pp. 245-254. Uses of nitrogen contained in discharge gases from gas engines in production of compounds of industrial importance. Paper before Nat Gas Assn. of America.

Petroleum

Studies on the Absorption of Light Oils from Gases, Harold S. Davis and Mary Davidson Davis, Jl. of Ind. & Eng. Chem., vol. 10, no. 9, Sept. 1918, pp. 718-725, 5 figs. Theory of washing process for the absorption of benzene vapor; determination of vapor pressure of benzene from its solution in high-boiling American petroleum oil; determination of average molecular weight of oil when dissolved in benzene by lowering freezing point; theory of washing processes for the absorption of light oil vapors.

Potash

The Recovery of Potash as a By-Product in the Manufacture of Portland Cement, John J. Porter. Am. Fertilizer, vol. 49, no. 5, Aug. 31, 1918, pp. 58-72. Possibilities of industry; problem of liberation; solubility of potash; electrical precipitation; estimating recovery; cost calculations.

Rubber

Comparative Methods for Determining the State of Cure of Rubber, H. P. Stevens. Jl. Soc. Chem. Ind., vol. 37, no. 16, Aug. 31, 1918, pp. 280T-284T, 5 figs. Formulation of degree of vulcanization in reference to (1) percentage of combined sulphur calculated in rubber present, (2) physical properties of vulcanizate, particularly load supported per unit cross sectional area at a given elongation, or vice-versa.

Moisture in Raw Rubber, G. Stafford Whitby. Jl. Soc. Chem. Ind., vol. 37, no. 16, Aug. 31, 1918, pp. 278T-280T, 1 fig. Records of observations made under tropical conditions on variations of water content of raw rubber and its relation to humidity of atmosphere, form of the rubber, and pressure of serum solids.

Sulphur

Sulphur from Coal. Gas. Jl., vol. 143, no. 2880, July 23, 1918, p. 159, 1 fig. German feld process for simultaneous recovery of sulphur and ammonia by washing coal gas with a solution of ammonium tetrathionate.

Sulphuric Acid

Some Observations on Sulphuric Acid Plants, New and Old (IV). Gas World, vol. 49, no. 1776, Aug. 3, 1918, pp. 18-19. Spent oxide as a source of sulphur; purification of coke-oven gas.

Sulphuric Acid in 1917, Philip S. Smith. Am. Fertilizer, vol. 49, no. 5, Aug. 31, 1918, pp. 78-86. Conditions of industry; uses; production; ores used in manufacture of acid.

The Thermal Properties of Sulphuric Acid and Oleum, Alfred W. Porter. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 373-399, 4 figs. and (discussion) pp. 399-400. Experimental data; formulæ and chart for determining heat of total evaporation for mixtures of sulphuric acid and water.

Water Softening

Increasing the Capacity of a Water Softener, C. R. Knowles. Ry. Maintenance Engr.,

vol. 14, no. 9, Sept. 1918, pp. 297-298, 4 figs. How railroad plant increased its capacity from 12,000 to 14,000 gal. per hr. by utilizing 100,000 gal. reservoir for storage of untreated water.

See also Cement and Concrete (By Products); Coal Industry (Coke); Engineering Materials (Rubber); Furnaces (Nitrogen-Fixation Furnaces); Refractories (High-Temperature Research), (Volatilization).

COAL INDUSTRY

By-Products

Liquid Fuel From Coal, W. R. Ormandy. Autocar, vol. 41, no. 1195, Sept. 14, 1918, pp. 257-258, 1 fig. The interrelation of pig iron, coke and benzol; report of Coal-Conservation Committee as affecting supply of fuel to motorists.

Coke

Pressure Regulation on By-Product Coke Ovens, Frederick H. Smoot. Gas World, vol 49, no. 1776, Aug. 3, 1918, pp. 19-20, 2 figs Valve arrangement and exhauster regulation. (From Iron Age, July 1, 1918.)

The Manufacture of Metallurgical Coke, With Special Reference to the Recovery of By Products, W. A. Bone. Iron & Coal Trades Rev., vol. 97, no. 2635, Aug. 30, 1918, p 231. Appendix to final report of Coal Conservation Committee specifying quality of coal best adapted for manufacture of metallurgical coke.

The New Coke Furnaces of the Thornaby Steel Mills, at Stockton-on-Tees, England, (Les nouveaux fours à coke des aciéries de Thornaby à Stockton-on-Tees) Génie Civil, vol. 72, no. 26, (whole no. 1872), June 29, 1918, pp. 469-472, 6 figs. Process for manufacturing metallurgical coke and recovering the by products.

Distillation

Low-Temperature Distillation of Illinois and Indiana Coals, G. W. Traer. Bul. Am. Inst. Min. Engrs., no. 141, Sept. 1918, pp. 1463-1470, 1 fig. Account of practical work directed toward commercial adaptation of principle demonstrated by Parr, namely, the caking bituminous coal when subjected to temperature less than 1000 deg. fahr. in a retort from which air has been excluded, will yield light tar of about 1.06 sp. gr. and high value; also, this yield with a given coal will depend upon percentage of hydrocarbons in coal, maximum temperature used, and promptness with which distillate gases are removed.

Fuel Conservation

Coal Conservation Committee's Final Report. Iron & Coal Trades Rev., vol. 97, no. 2634, Aug. 23, 1918, pp. 199-200. Report of Mining Sub-Committee on Proposed Ministry of Mines and Minerals.

Loss and Waste in Coal Production. Iron & Coal Trades Rev., vol. 97, no. 2634, Aug. 23, 1918, pp. 227-230. From final report of Coal Conservation Committee.

Statistics

Coal in 1916, C. E. Lesher. U. S. Geol. Survey, II: 35, Mineral Resources of the United States, 1916-Part II., Aug. 17, 1918, pp. 901-991. Statistics of production, distribution and consumption in United States.

CONCRETE

(See Cement and Concrete)

CONVEYING

(See Hoisting and Conveying)

ELECTRICAL ENGINEERING

Alternators

The Behavior of Alternators with Zero Power-Factor Leading Current, F. D. Newbury. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp 363-365, 3 figs. Curves showing excitation characteristics and saturation conditions required for stable self-excitation.

Cables

Aerial Cable Construction for Electric Power Transmission, E. B. Meyer. Elec. News, vol. 27, no. 17, Sept. 1, 1918, pp. 25-27, 4 figs. Design, construction and suspension of special cable used by company supplying light and power to 170 manufacturing plants. Paper before Am. Inst. Elec. Engrs.

Control Systems

Automatically Remote Controlled Synchronous Motor Generator Substation, William Thomas Snyder. Elec. Rev., vol. 73, no. 11, Sept. 14, 1918, pp 407-409, 5 figs. Relative cost of automatic and manually-operated substation and mode of operating such a station of 100 kw. capacity.

Control System for Groups of Motors in a Cement Mill, William H. Easton. Eng. & Cement World, vol. 13, no. 5, Sept. 1, 1918, pp. 61-62, 3 figs. Group of eleven motors—nine 150 H.P. 2200 volt, Westinghouse squirrel-cage motors, driving 5½ by 22 ft. tube mills, and two 250 H.P., 2200-volt Westinghouse vertical squirrel-cage motors, cement-mill type, driving Bradley grinders, controlled by system recently installed.

Electromagnets

D. C. Lifting Magnets (Electro-aimants de levage à courant continu), J. A. Montpellier. L'Industrie Electrique, year 27, no. 628, Aug. 25, 1918, pp. 305-307, 3 figs. Characteristics of each one of the five types built by the Société l'Eclairage Electrique.

Excessive Voltages

Insulation and Damages from Excessive Potentials (Isolation och öfverspanningsskydd), W. Borggvist. Elektroteknik, vol. 48, no. 8, Aug. 1918, pp. 95-96, 1 fig.

The Evolution of the Problem of Excessive Voltages During the Last Years (Öfverspänningsfragans utveckling under de senaste åren), E. Alm. Elektroteknik, vol. 48, no. 8, Aug. 1918, pp. 91-95, 14 figs. (Concluded.)

The Protection of Electrical Apparatus, P. M. Lincoln. Elec Jl., vol. 15, no. 9, Sept. 1918, pp. 316-318 Brief review of various methods by which integrity of electrical insulation may be secured and permanently assured.

Heating of Conductors

Investigation of Heating of Conductors, Henry C. Horstman and Victor Tousley. Elec. World, vol. 72, no. 11, Sept. 14, 1918, pp. 489-490, 2 figs. Evidence indicates that National Electric Code rating should be modified to permit use of smaller conductors where load is intermittent; data on heating produced by continuous loads.

Inductive Capacity

Change of Specific Inductive Capacity with Temperature and Impregnation of Paper, H. C. P. Weber and T. C. MacKay. Jl. Franklin Inst., vol. 186, no. 3, Sept. 1918, pp. 374-377, 2 figs. Curves showing results obtained for various substances alone and in conjunction with impregnated paper, at Westinghouse Elec. & Mfg. Co.'s laboratory.

Lighting

Electric Lighting from Three-Phase Circuits, Terrell Croft. Southern Engr., vol. 30, no. 2, Oct. 1918, pp. 44-48, 14 figs. Suggestions for laying out systems, transformers and auto-transformers; industrial applications.

Motors

A Large Rolling-Mill Motor. Elec. Times, vol. 54, no. 1398, Aug. 1, 1918, pp. 74-75, 3 figs. Features of electrification of Frodingham Iron and Steel Works.

Causes of Overheated Motors and Motor Noises, M. A. Saller. Southern Engr., vol. 30, no. 2, Oct 1918, p. 49. Improperly fitted or tight bearings, defective oil rings, unequal air gap, small brushes.

High-Power Factor Induction Motors, Marius Latour. Elec. World, vol. 72, no. 11, Sept. 14, 1918, pp. 484-489, 19 figs. Summary of various arrangements for variable-speed motors of above description proposed in last 15 years, with particular reference to French developments.

How to Buy Direct-Current General-Utility Motors, A. Brunt. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 532-534, 6 figs. Suggestions for Buyers.

Low Over-All Cost and Continuous Production, A. F. Lewis. Elec. World, vol. 72, no. 13, Sept. 28, 1918, pp. 592-595, 5 figs. Factors that must be considered in purchasing, installing and maintaining induction motors designed to assist in these objects.

Oerlikon Three-Phase, Low-Speed, Variable-Speed Motors with large Flywheel Effect, for Direct Coupling to Mine Ram Pumps. Elecn., vol. 81, no. 2101, Aug. 23, 1918, pp. 352-354, 7 figs. General description with diagrams and illustrations.

Recording Instruments

The Use of Graphic Instruments in Improving the Operation of Electrical Apparatus and Reducing Cost of Maintenance, J. H. Overpeck. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 354-357, 3 figs. Forms for keeping records of motor failures.

Safety Measures

Installation and Care of Large Electrical Apparatus for Steel Mills, O. Needham. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 333-336 2 figs. Insulation protection; handling, storing, erecting and starting; operation and care.

Substations

Large Underground Synchronous Substation, R. P. Hines. Coal Age, vol. 14, no. 10, Sept. 5, 1918, pp. 434-436, 4 figs. Description of substation in bituminous coal mine and its equipment.

Largest Portable Substation Yet Produced, B. H. Lytle. Elec. Ry. Jl., vol. 52, no. 11, Sept. 14, 1918, pp. 467-468, 6 figs. Long Island Railroad's portable substation used in parallel with permanent substations to help with excessive loads or as a separate substation.

Transformers

The Essentials of Transformer Practice (XIV), E. G. Reed. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 365-367, 3 figs. Formulæ for calculations of electrical quantities in reactors with magnetic circuit either of air or iron.

Transformer Connections, Waldo Bennett. Southern Engr., vol. 30, no. 2, Oct. 1918, pp. 52-53, 9 figs. Relations of windings in single, two- and three-phase; special connections.

Transient Phenomena

Some Transient Phenomena in Electrical Supply Systems, E. W. Marchant. Jl. Instn. E. E., vol. 56, no. 276, July 1918, pp. 445-455, 17 figs. and (discussion), pp. 455-471, 7 figs. Records oscillograms taken on Liverpool Corporation electric supply system. Also tests of similar phenomena under laboratory conditions.

Turbo-Generators

High Speed Turbo-Generators. Practical Engr., vol. 58, no. 1645, Sept. 5, 1918, pp. 114-116, 6 figs. Details of construction of rotors and stators. (Continued.)

Voltage Regulation

Improving Power Factor and Voltage Regulation, J. T. Peyton. Elec. World, vol. 72, no. 11, Sept. 14, 1918, pp. 492-493, 3 figs. By using synchronous condensers, a Pennsylvania company has met increased demand without additional generating equipment and has reduced transmission losses.

See also Furnaces (Electric Brass Furnaces), (Induction Furnaces), (Resistance Furnaces); Heating and Ventilation (Electric Heating Units), (Turbo-Generator Ventilation); Machine Shop (Welding); Marine Engineering (Electrical Machinery); Military Engineering (Electrical Machinery), (Sub-stations); Steel and Iron (Electric Steel).

ENGINEERING MATERIALS

Aluminum

The Alterability of Aluminum and the Properties of Its Various Alloys, Jean Escard. Sci. Am. Supp., vol. 86, no. 2225, pp. 127-128. Factors affecting alterability; properties of commercial aluminum; alteration as determined by Le Chatelier; uses and requirements; aluminum bronzes; other alloys. From Revue Scientifique.

Asphalt

Standardization of Required Consistency for Asphalt, J. R. Draney. Good Roads, vol. 16, no. 14, Oct. 5, 1918, p. 131. Reviews present practice and suggests standardization. (Am. Soc. Mun. Improvements.)

Boiler Plates

A Cause of Failure in Boiler Plates, Walter Rosenhain and D. Hanson. Iron Age, vol. 102, no. 11, Sept. 12, 1918, pp. 632-636, 15 figs. Effect of grain growth; alteration of crystalline structure by mechanical deformation; some remedies. (Iron & Steel Inst., London, May 1918.)

Are There Advantages in Welding Boiler Plate? Howard L. Boyd. Power, vol. 48, no. 14, Oct. 1, 1918, pp. 504-506, 7 figs. Dangers of using metal for welding boiler plate which is of a chemical composition different from that of metal in plates. From California Safety News of Industrial Accident Commission of Cal.

Causes of Failure in Boiler Plates, Walter Rosenhain and D. Heinsen. Marine Eng. of Can., vol. 8, no. 9, Sept. 1918, pp. 225-228, 15 figs. Effect of grain growth; alteration of crystalline structure by mechanical deformation; suggested remedies. Iron & Steel Inst. paper.

Bronze

The Microstructure and Value of Manganese Bronze. Shipbuilding & Shipping Rec., vol. 12, no. 10, Sept. 5, 1918, pp. 232-234, 1 fig. Values of alloy in each of two sources of introducing manganese into bronze, copper and manganese, and ferromanganese.

Copper

The Action of Reducing Gases on Hot Solid Copper, Norman B. Pilling. Jl. Franklin Inst., vol. 186, no. 3, Sept. 1918, pp. 373-374. Report of results obtained at research laboratory of Westinghouse Elec. & Mfg. Co.

Hardness

Hardness of Soft Iron and Copper Compared, F. C. Kelley. Gen. Meeting Am. Electrochem. Soc., Oct. 2, 1918, Advance Copy, Paper 3, pp. 45-48. Results of hardness tests applied by Brinell method on samples of American "ingot iron" and ordinary commercial cold-rolled copper after being similarly treated in an electrically heated vacuum furnace.

Rubber

Rubber Substitutes, Andrew H. King. India's Rubber Jl., vol. 56, no. 6, Aug. 10, 1918, pp. 145-146. Factors and limitations of asphaltic materials; coal-tar and asphalt pitches; resinous substances; glue. (Concluded from preceding issue.)

Semi-Steel

Tracing the Development and Use of Semi-steel. Can. Machy., vol. 20, no. 11, Sept. 12, 1918, p. 319. Uses in munition manufacture in France, and in auto and truck trade.

See also Aeronautics (Materials of Construction); Refractories.

FACTORY MANAGEMENT

Compensation

Forms for Use in Recording Compensation, Coal Age, vol. 14, no. 11, Sept. 12, 1918, pp. 506-508. How to keep records which will stimulate foremen and others and make it possible to ascertain the probable effect, in cost of self-insurance, of any change in legislation.

Cost Systems

Cost System for a Medium Size Foundry, D. O. Barrett. Iron Age, vol. 102, no. 14, Oct. 3, 1918, pp. 810-813, 11 figs. Various forms which have proved their usefulness after several years' experience following a period of financial loss.

Proper Factory Cost Accounting Methods, Joseph Mack. Am. Industry, vol. 19, no. 2, Sept. 1918, pp. 17-18. How to distribute overhead expenses. Address before International Assn. of Mfg. Photo-Engravers.

Drafting Department

Drawing-Room System in the Engineering Department, G. F. Hamilton. Am. Mach., vol. 49, no. 11, Sept. 12, 1918, pp. 485-487, 10 figs. Method for recording drawings and insuring correction of copies sent into shop.

Organization and Wage Payment for the Drafting Department, J. B. Conway. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 555-558, 4 figs. Description of plan in practical operation under conditions similar to those set forth in the article.

Production

Graphic Production Control, C. E. Knoeppel. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 177-180, 2 figs. First of series. Underlying and basic principles.

Keeping Track of Production, H. A. Russell. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 231-234, 4 figs. Key to methods described is a summary card, the production-operation cost record, upon which are entered all vital facts in regard to progress of every manufacturing order, and upon which is also kept a running inventory of all parts in stock.

Production Comparisons, Walter D. Fuller. Gas Industry, vol. 18, no. 7, July 1918, p. 241. Methods employed for determining actual and possible production.

Rents

Overhead Rent. Gas Industry, vol. 18, no. 7, July 1918, p. 239. Plan for distributing all expenses incident to occupying buildings and grounds for manufacturing, storage and office purposes.

Salvage

Salvage at the Winchester Plant, Charles M. Horton. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 201-204, 8 figs. How scrap and spare material to annual value of millions of dollars is reclaimed and utilized.

Small Jobs

Reducing the Time Occupied in Doing the Small Job. Ry. Maintenance Engr., vol. 14, no. 9, Sept. 1918, pp. 299-302. Five discussions of work done by bridge and building departments of different railroads.

Stores

Efficiency in the Handling of Railway Supplies, Charles E. Parks. Ry. Age, vol. 65, nos. 10 and 11, Sept. 6 and Sept. 13, 1918, pp. 423-427, 3 figs., pp. 491-493. Sept. 6: Methods employed by Santa Fe in storing, handling, distributing and accounting for material. Sept. 13: Line stock; ordering material; surplus and obsolete material; inventories.

Railway Stores Methods and Problems, W. H. Jarvis. Ry. Gaz., vol. 29, nos. 6 and 7, Aug. 9 and Aug. 16, 1918, pp. 155-158, and pp. 181-184, Aug. 9: Method of dealing with invoices; four-weekly balance sheets; issuing prices. Aug. 16: Stock inventories; stores sold accounts; auditing and verification of stocks.

Waste

The Elimination of Waste. Cassier's Eng. Monthly, vol. 54, no. 3, Sept. 1918, pp. 143-149. Suggestions as to how industrial waste can be cut down and scrap material reclaimed.

See also Lighting (Factory Lighting).

FORGING

Drop Forging

Drop Forging in Automobile and Aircraft work. Automobile Engr., vol. 8, nos. 116 and 118, July and Sept. 1918, pp. 190-192, 16 figs., pp. 261-263, 10 figs. Details of typical plant, with description of modern tools necessary for drop forging and methods.

Forging Machine

Possibilities of the Forging Machine, E. R. Hagen. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 304-305, 2 figs. Uses of the upsetter machine in railroad and locomotive shops.

Fuel

Fuel Analysis of a Drop Forge Plant (1), B. K. Read. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 307-312, 3 figs. Charts showing daily fuel and power consumption, results of installing new heating equipment, steam consumption on hammers and cost of steam in dollars per hammer-hour. From paper before Am. Drop Forge Assn.

Hammer Foundations

Question of Correct Hammer Foundations, Terrell Croft. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 300-304, 4 figs. Discussion of functions of hammer foundation; results of poor installation; designs and data for different types.

Piston Rods

The Care and Maintenance of Piston Rods, G. C. Stebbins. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 298-299, 1 fig. Information regarding treating of piston rods; explanation of central oiling system and its relation to maintenance of hammers. Before Am. Drop Forge Assn.

FOUNDRY

Brass Castings

How Brass Carburetors are Molded and Cast. Foundry, vol. 46, no. 10, Oct. 1918, pp. 465-469, 10 figs. Molding machines of jar-ram squeeze type extensively employed; workmen held responsible for quality of product.

Centrifugal Casting

Casting Rings in Centrifugal Machine, E. P. Cone. Iron Age, vol. 102, no. 14, Oct. 3, 1918, pp. 801-807, 8 figs. Large quantity production by De Lavaud process; unusual properties of metal.

Core Sand

Suggestions on Mixing Foundry Core Sand, Robert Crimshaw. Iron Age, vol. 102, no. 14, Oct. 3, 1918, pp. 807. Analysis of method for securing best porosity and strength in cores.

Die Castings

The Design of Die Castings, M. Stern. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 549-551, 3 figs. Practical suggestions for designer.

Fluidity of Iron

The Fluidity of Molten Cast Iron, Matthew Riddell. Foundry Trade Jl., vol. 20, no. 199, July 1918, pp. 364-366, 1 fig. Attempt to explain peculiarity of cupola observed by author, which consists in greater fluidity being obtained when the bed coke is not well lighted above the tuyeres before the blast is put on and the first iron takes long to come down. Paper before British Foundrymen's Assn.

Foreign Methods

American and Foreign Steel Foundries. Iron Age, vol. 102, no. 14, Oct. 3, 1918, pp. 808-809. A British comparison of French, Belgian and American steel castings; our molding and annealing called inferior.

Foundry Industry

Foundry Industry Makes Big Gain in Two Years. Foundry, vol. 46, no. 10, Oct. 1918, pp. 455-460, 7 figs. Statistics on growth of foundries.

Foundry Losses

How the Engineer Stops Foundry Losses, Stephen B. Phelps. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 209-211, 6 figs. Defective castings, a total loss of foundry labor and supplies, can be prevented by proper design.

Man Power

Your Biggest Foundry Problem—Man-power, H. Cole Estep. Foundry, vol. 46, no. 10, Oct. 1918, pp. 443-450, 13 figs. War demands more castings with less labor; machines must do work of men.

Patterns

Mounting Patterns on Plates an Aid to Molding, R. R. Clarke. Foundry, vol. 46, no. 10, Oct. 1918, pp. 451-454, 3 figs. Various methods described and their advantages and disadvantages discussed from standpoint of both foundryman and patternmaker.

Taking the Pattern Shop Out of the Attic, F. L. Prentiss. Iron Age, vol. 102, no. 11, Sept. 12, 1918, pp. 640-641, 2 figs. Cleveland patternmaker believes business should be banished from dingy quarters and puts his ideas into practice.

The Making of Better Patterns, Ellsworth Sheldon. Am. Mach., vol. 49, no. 14, Oct. 3, 1918, pp. 617-629, 10 figs. Requirements of a good patternmaker.

Steel Castings

Steel Castings Design and Manufacture. Foundry Trade Jl., vol. 20, no. 199, July 1918, pp. 375-378. Discussion of paper presented before British Foundrymen's Assn., published in June issue.

The Manufacture of Steel Castings, E. F. Lange. Foundry Trade Jl., vol. 20, no. 199, July 1918, pp. 372-374. Comparison of American with European standards and practice. (Sequel to Development in the Manufacture of Steel Castings, Feb. 1917.)

Vents

Venting Moulds and Cores, S. G. Smith. Foundry Trade Jl., vol. 20, no. 199, July 1918, pp. 367-371, 18 figs. Suggestions to apprentices on proper manner of providing passages for free escape of expanded air and gases.

See also Steel and Iron (Semi-Steel).

FUELS AND FIRING

Air Proportions

Calculating the Excess of Air Used in Combustion, V. Hassreidter. Gas Jl., vol. 143, no. 2881, July 30, 1918, p. 206. States that when volume, G, of producer gas is burned, volume of air required is not $R-G$, but $R-g-c-d$ where R is volume of products of combustion, c contraction and d expansion due to combustion. (Jl. Soc. Chem. Ind.)

Alcohol

Alcohol as Power Fuel. Gas & Oil Power, vol. 13, no. 155, Aug. 1, 1918, pp. 159-160. Account of research in production and adaptation of alcohol for power-fuel purposes carried out in Australia by a special committee under Commonwealth Advisory Council of Science and Industry.

Bituminous Coal

Burning Bituminous Coal in House-Heating Boilers, W. A. Pittsford. Heat. & Vent. Mag., vol. 15, no. 9, Sept. 1918, pp. 23-27, 15 figs. From address before Smoke Prevention Assn., Newark, Aug. 1918.

Method of Fixing Prices of Bituminous Coal Adopted by the United States Fuel Administration, C. Garnsey, R. V. Norris, and J. H. Allport. Bul. Am. Inst. Min. Engrs., no. 141, Sept. 1918, pp. 1411-1433, 6 figs. Discussion of four methods considered by Engineers' Committee: namely, actual cost at colliery plus fixed sum or percentage; actual cost at colliery plus graduated profit decreasing as costs increase; prices fixed on average cost in each district; all coal sold at average cost of district plus profit, and return to colliery adjusted through clearing house at price proportioned to cost of production.

Carbon Dioxide

Placing CO₂ on Financial Basis. Eng. & Cement World, vol. 13, no. 4, Aug. 15, 1918, pp. 62-64. Chart to estimate money lost up the stack due to low carbon dioxide, prepared for use of central-station engineers.

Coal Storage

Coal Storage in Large Quantities, Henry J. Edsall. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 193-200, 20 figs. Methods, equipment and typical installations, diagrams of arrangements of tracks and piles.

Handling Roundhouse Coal. Power, vol. 48, no. 11, Sept. 10, 1918, pp. 372-375, 10 figs. Describes modern coal-handling system of belt conveyors for stocking and conveying coal to bins for locomotive and boiler-room use, installed at new Croxton roundhouse of Erie R. R.; capacity, 100 tons per hr.

Physical and Chemical Changes in Stored Coal. Gas Age, vol. 42, no. 6, Sept. 16, 1918, pp. 245-247, 5 figs. Results of tests. Translated from Revue Générale de l'Electricité.

Public Utility Experience in Coal Storage. Gas Age, vol. 42, no. 5, Sept. 2, 1918, pp. 193-196, 6 figs. Reports from various companies, secured by Univ. of Ill.

Reinforced Concrete Coal Storage Plant, H. C. Campbell. Eng. & Cement World, vol. 13, no. 5, Sept. 1, 1918, pp. 13-15, 5 figs. Description of pockets or storage bins especially designed for requirements, capacity and location.

Spontaneous Combustion of Stored Coal, S. H. Katz. Gas Age, vol. 42, no. 5, Sept. 2, 1918, p. 200. Results of experiments showing importance of proportion of voids in a mass of stored coal exposed to air. From Tech. Rep. 170, U. S. Bureau of Mines.

Storage and Handling of Gas Coal, H. H. Stock. Gas Age, vol. 42, nos. 5 and 6, Sept. 2, and Sept. 16, 1918, pp. 207-210, 9 figs., and pp. 255-258, 10 figs. Review of investigations by Experiment Station of Univ. of Ill. Deals with locomotive crane storage; circular storage; steeple towers; Hunt System; bridge storage; swivel bridge; expense of storing.

The Storage of Bituminous Coal, John H. Anderson. Power, vol. 48, no. 9, Aug. 27, 1918, pp. 321-322. Suggestions based on author's examination of piles on fire. Paper before Inst. of Marine Engrs.

Coal Valuations

An Alinement Chart for the Evaluation of Coal, A. F. Blake. La. Planter & Sugar Manufacturer, vol. 61, no. 10, Sept. 7, 1918, pp. 156-157. Designed to determine relative values of different coals, given price per ton and chemical analysis, by calculating the relative costs of a million heat units in accordance with the methods established by U. S. Bureau of Mines.

Combustion Losses

Combustion Losses and Their Minimization (III), Robert June. Brick & Clay Record, vol. 53, no. 6, Sept. 10, 1916, pp. 465-468, 2 figs. Heat losses in burning coal; in the dry chimney gases; due to incomplete combustion; in fuel through grate; due to superheating moisture in air and to moisture in fuel; due to visible smoke and to radiation.

Losses in the Boiler Room From Incomplete Combustion and High Stack Temperature, George H. Diman. Textile World Jl., vol. 54, no. 14, Oct. 5, 1918, pp. 82 and 87, 2 figs. Tables calculated from average conditions in New England textile mills.

Danish Fuels

Concerning Our (Danish) Fuels (Om vore Brændselsstoffer), Gunnar Jergensen. Ingenioren, vol. 27, no. 66, Aug. 17, 1918, pp. 451-459.

Fuel Changes

Problems Involved in Fuel Changes, A. Bement. Power, vol. 48, no. 11, Sept. 10, 1918, pp. 380-382. Ash, not coal, the trouble maker; operatives do not change method of firing with coal. Some concrete instances and the remedies.

Fuel Conservation

Bulletin for Firemen and Engineers. Textile World Jl., vol. 54, no. 14, Oct. 5, 1918, pp. 81-82. Bul. no. 3 of Mass. Fuel Administration prepared by a committee of operating engineers and firemen.

Coal Conservation Committee, Final Report. Colliery Guardian, vol. 116, no. 3008, Aug. 23, 1918, pp. 385-388, 1 fig. Final report of committee appointed in 1916 by Mr. Asquith issued by Ministry of Reconstruction.

Coal Saving Suggestions and a Few Don'ts. Aera, vol. 7, no. 2, Sept. 1918, pp. 179-180, 1 fig. Suggestions based on experience of Westinghouse Elec. & Mfg. Co.'s combustion engineers.

Conservation of Fuel Used by Public Utilities, L. R. Nash, E. B. Powell and H. Vittinghoff. Stone & Webster Jl., vol. 23, no. 3, Sept. 1918, pp. 163-177. Considers load ing and operation improvements for reducing fuel consumption to minimum by gas, electric light and power companies and railroads.

Fuel Saving in Massachusetts. Aera, vol. 7, no. 2, Sept. 1918, pp. 107-118. Method in vogue which, it is assured, will save 260,000 tons of coal during present year.

Practical Fuel Conservation, F. C. Wagner. Nat. Engr., vol. 22, no. 9, Sept. 1918, pp. 401-404. Stationary engineer's part in campaign to conserve coal; suggestions regarding equipment and operation. Paper before Ind. State Convention, Nat. Assn. Stationary Engrs.

Report of Coal Conservation Committee. Engineer, vol. 126, no. 3269, Aug. 23, 1918, p. 158, 2 maps.

Fuel Supplies

Is Our Fuel Supply Nearing Exhaustion? R. H. Fernald. Ry. Rev., vol. 63, no. 8, Aug. 24, 1918, pp. 271-275. Digest of fuel resources of the world and particularly of United States, giving statistical data as to rates of production, rates of depletion, and prospects of exhaustion. From Gen. Elec. Rev.

Furnaces

Combustion and Smokeless Furnaces, Joseph W. Hays. Steam, vol. 22, no. 3, Sept. 1918, pp. 65-70. Discussion based on nature and properties of heat and on Berthelot's Second Law regarding heat produced in a furnace. (To be continued.)

Gas Firing

Gas Firing for Boilers, T. M. Hunter. Elec. Times, vol. 54, no. 1398, Aug. 1, 1918, pp. 73-74. Remarks on advisability of firing boilers with gas. Paper before South Wales Inst. of Engrs.

Low-Grade Fuels

Experience with the Combustion of Lignites, R. A. Ross. Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 208-210. Experiments at Saskatoon plant.

Method for the Combustion of Brown Coal. Marine Eng. of Can., vol. 8, no. 9, Sept. 1918, p. 241. Brief note on process based on applying conditions in water-gas producer to boiler furnace and using exhaust steam for gas production.

Suggestions for Efficiently Burning Lignites in a Domestic Furnace, R. G. McLaurin. Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 210-213, 1 fig. Prerequisites for efficient combustion of western coal are new furnace design, and control of combustible and air.

The Use of Lignite, Bagasse and Wood Waste for Power Generation and Other Purposes, John B. C. Kershaw. Engineer, vol. 126, no. 3268, Aug. 16, 1918, pp. 133-134. (Second article.)

Low-Rate Combustion

Getting Fuel Economy Under Difficulty. Black Diamond, vol. 61, no. 13, Sept. 28, 1918, p. 249. Suggestions to save coal while under low-rate combustion in hand-fired plants. From Tech. Paper No. 139, Low-Rate Combustion in Fuel Beds of Hand Fired Furnaces, Bureau of Mines.

New England

The Fuel Situation in New England, Charles T. Main. Power, vol. 48, no. 14, Oct. 1, 1918, p. 508. From paper before New England Water Works Convention, Sept. 1918.

Oil Storage

Losses of Oil in Storage, C. P. Bowie. Jl. Soc. Automotive Engrs., vol. 3, no. 3, Sept. 1918, pp. 235-237. Data of losses by evaporator and from wooden and steel rod tanks; devices for lessening losses. From Oil Storage Tanks and Reservoirs, Bul. 155 (Petroleum Technology 11) of the Bureau of Mines.

Peat

Coal Conservation, Gas Producer Economies. Gas & Oil Power, vol. 13, no. 156, Sept. 5, 1918, pp. 167-168. Utilization of peat fuels in production of gas for suction engines.

The Value of Peat Fuel for the Generation of Steam. Engineer, vol. 126, nos. 3269 and 3270, Aug. 23 and Aug. 30, 1918, pp. 163-166, 6 figs., and pp. 178-180, 4 figs.

The Utilization of the Peat Resources of Canada, B. F. Haanel. Jl. Soc. Chem. Industry, vol. 37, no. 15, Aug. 15, 1918, pp. 258T-261T. Canadian peat deposits; description of peat; cost of manufacture; utilization for industrial purposes; peat as a source of oil and retort gas.

Pulverized Coal

A Diversified Application of Powdered Coal, Charles Longnecker. Iron Age, vol. 102, no. 11, Sept. 12, 1918, pp. 619-623, 8 figs. Pulverized fuel, distributed by compressed air to substations, used in open-hearth, annealing and other furnaces.

Fuels, E. R. Knowles. Steam, vol. 22, no. 3, Sept. 1918, p. 76. Four requirements in burning of pulverized coal and attainable with it. (Concluded from August issue.)

Powdered Coal Cuts Coal Consumption in Annealing Ovens Thirty Per Cent. Can. Machy., vol. 20, no. 9, Sept. 5, 1918, p. 300, 1 fig. Brief account of recent work done at malleable-iron plant of Am. Radiator Co., Buffalo.

Pulverized Coal Firing. Iron & Coal Trades Rev., vol. 97, no. 2636, Sept. 6, 1918, p. 265, 1 fig. Particulars of system developed by Fuller Engineering Co.

The Possibilities of Powdered Coal as Shown by Its Combustion Characteristics, W. G. Wilcox. Steam, vol. 22, no. 3, Sept. 1918, pp. 70-75. Requirements necessary in perfect combustion, weaknesses of present methods; conclusions regarding powdered coal. Paper before N. Y. Section, Am. Chem. Soc.

Soft Coal

Burning Soft Coal in Heaters Designed for Hard Coal. Heat. & Vent. Mag., vol. 15, no. 9, Sept. 1918, pp. 21-23. Suggestions for selecting and using coal for house-heating equipment.

Stokers

Handling Jones Under-Feed Stokers, "Receiver." Power Plant Eng., vol. 22, no. 18, Sept. 15, 1918, pp. 743-744, 4 figs. Building and banking fires; precautions to observe in handling fires.

Smokeless Combustion with Chain-Grate Stokers, Thomas A. Marsh. Elec. Rev., vol. 73, no. 12, Sept. 21, 1918, pp. 448-449, 2 figs. Discussion of furnace chambers, boiler settings and baffling as affecting efficiency and smokeless combustion of high-volatile coals. Paper before Annual Smoke Prevention Convention, Newark, N. J.

The Stoker of the Future, Joseph Harrington. Elec. Rev., vol. 73, no. 12, Sept. 21, 1918, pp. 442-443. Analysis of mechanical-stoker evolution as influenced by coal characteristics, clinker, efficiency and rate of combustion.

Wood

Wood Fuel, A. Barbey. Domestic Eng., no. 277, Sept. 1918, pp. 1-3. Present situation in Switzerland. Paper before Vaudoise Soc. of Nat. Sci. From Bulletin Technique.

See also Forging (Fuel); Coal Industry (Fuel Conservation); Hoisting and Conveying (Coal Handling); Mines and Mining (Shale Oil); Motor-Car Engineering (Fuels).

FURNACES

Electric Brass Furnace

A Rocking Electric Brass Furnace, H. W. Gillett and A. E. Rhoads. Brass World, vol. 14, no. 9, Sept. 1918, pp. 264-268. Description of furnace at plant of Michigan Smelting & Refining Co., with results of tests and bibliography of electric-furnace literature.

Gas Heat-Treating Furnace

Automatic Shell Heat Treating Furnaces, W. J. Harris, Jr., Iron Age, vol. 102, no. 10, Sept. 5, 1918, pp. 565-568, 8 figs. Human element superseded by mechanical devices in a new gas-fired installation at Pawtucket.

Induction Furnaces

Production of High Temperature and Its Measurement, E. F. Northrup. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 212-221, 6 figs. Principle of operation and details of a 20-kw. electric induction simple crucible furnace.

Nitrogen-Fixation Furnaces

Nitrogen Fixation Furnaces, E. Kilburn Scott. Gen. Meeting Am. Electrochem. Soc., Oct. 2, 1918, Advanced Copy, Paper 8, pp. 103-134, 17 figs. Review and comparison of various types of electrical furnaces; description of author's three-phase furnace and discussion of its details in comparison with other types.

Resistance Furnaces

Tests on a Resistance Electric Furnace for High Temperatures (Försök med en elektrisk motstandsugn för höga temperaturer), Jakob Forssell. Teknisk Tidskrift,

vol. 48, no. 66, July 24, 1918, pp. 93-98, 4 figs.

HEATING AND VENTILATION

Electric Heating Units

Electricity as a Substitute for Gas, Frank Thornton. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 324-325. Comparison of electricity as heating unit with natural gas and coal; conditions which have developed electrical heating. From paper before Engrs.' Soc. of Western Pa. (To be Continued.)

Equipment

Care of Heating and Ventilating Equipment, Harold L. Alt. Power, vol. 48, no. 11, Sept. 10, 1918, pp. 383-384. First of series on economical operation.

Factories

Difficult Problems of Paper Manufacturers Solved by the Sturtevant Absorption System. Paper Mill, vol. 41, no. 40, Oct. 5, 1918, pp. 16 and 44-46, 3 figs. Heating and ventilating system of large mill.

Factory Heating, Chas. L. Hubbard. Steam, vol. 22, no. 3, Sept. 1918, pp. 63-65. Methods of computing available exhaust-and live-steam requirements. (To be continued.)

Heating and Ventilating Are Very Important (II), M. H. Potter. Can. Machy., vol. 20, no. 8, Aug. 22, 1918, pp. 225-227, 6 figs. Systems of heating buildings; machine-shop arrangements; suitable temperatures; artificial lighting.

Heating Systems

Fuel Saving Heating Systems, Alfred G. King. Domestic Eng., vol. 84, no. 8, pp. 272-274, 5 figs. How the vapor-vacuum system is installed; how it operates and how fuel is conserved.

Heating and Piping Systems. Contract Rec., vol. 32, no. 37, Sept. 11, 1918, p. 740. Points to be considered in design of a heating system.

Pressure Regulation

Pressure Regulating Devices, Chas. L. Hubbard. Domestic Eng., vol. 84, no. 9, Aug. 31, 1918, pp. 312-314, 7 figs. Notes on construction and operation of pressure-reducing valves for modern heating systems. (To be continued.)

School Buildings

School Building Heating and Ventilation, Samuel R. Lewis. Heat. & Vent. Mag., vol. 15, no. 9, Sept. 1918, pp. 33-43, 14 figs. Second article.

Turbo-Generator Ventilation

The Ventilation of Turbo-Generators, J. Humphrey. Iron & Coal Trades Rev., vol. 97, no. 2636, Sept. 6, 1918, pp. 260-261, 1 fig. Deal chiefly with question of dust removal from air.

See also Fuels and Firing (Low-Grade Fuels).

HOISTING AND CONVEYING

Chains

Safe Chain Loads, A. Black. Machy., vol. 25, no. 1, Sept. 1918, pp. 37-39. Factors that determine safe loads and effects obtained by annealing chains.

The Manufacture and Testing of Cast Steel Chain Cables. Page's Eng. Weekly, vol. 33, no. 728, 1918, pp. 88-90. Memorandum issued by Lloyd's register of shipping.

Coal Handling

A New Design for Engine Coaling Facilities. Ry. Age, vol. 65, no. 14, Oct. 4, 1918, pp. 615-616, 2 figs. Economies effected in track capacity and car supply on Erie R. R.

Coal and Shipping. Transport from Collieries to Ports, F. J. Warden-Stevens. Colliery Guardian, vol. 116, no. 3009, Aug. 30, 1918, pp. 439-440. Description of means and equipment for shipping coal from mines to ports in the United Kingdom.

Concrete Coal Bins Prove Profitable, C. W. Hull. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, pp. 23-24, 2 figs. Record of successful operation and methods of unloading from cars and loading trucks.

Coal Tipples

Simpson Creek Coal Company's Tipples, R. G. Read. Coal Age, vol. 14, no. 11, Sept. 5, 1918, pp. 430-433, 5 figs. Features of design described and illustrated.

Conveyors

Conveyor at the Wellpark Brewery, Glasgow. G. F. Zimmer. Engineering, vol. 106, no. 2746, Aug. 16, 1918, pp. 165-168, 15 figs. Illustrated description of a combination push-bar or drag link conveyor and the roller runway.

Conveyors for Chemical Works, William H. Atherton. Conveying (Supp. to Cassier's Eng. Monthly), vol. 1, no. 4, Sept. 1918, pp. xxix-xxxiv, 9 figs. General arrangement of plant for handling granulated niter cake. (Continuation of serial.)

Conveyors, Robert S. Lewis. Min. & Sci. Press, vol. 117, no. 11, Sept. 14, 1918, pp. 349-355, 8 figs. Data for designing and calculating belt-conveyor systems.

Portable Automatic Trimming Conveyor, Geo. F. Zimmer. Conveying (Supp. to Cassier's Eng. Monthly), vol. 1, no. 4, Sept. 1918, pp. xxxv-xl, 6 figs. Device to handle coal with minimum expenditure of manual labor to trim it uniformly over the available bunker space provided in naval, mail and cargo steamers.

Cranes

Industrial Controllers (XXI), H. D. James. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 368-371, 12 figs. Electrical operation of cranes; diagrams of connections; design features of various types.

Elevators

Development of V-Groove Elevator, Charles Reedy. Nat. Engr., vol. 22, no. 9, Sept. 1918, pp. 410-413. History of experiments; discussion of various makes of traction drives; features of operating costs and details. Abstract of paper before convention of Elevator Mfrs.' Assn.

Mine Locomotives

A New Type of Mine Locomotive Controller, L. W. Webb. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 620-622, 8 figs. Pneumatic hand-operated control for electric power equipments.

Ore Cars

Ore Car Designed at Hecla Mine, C. T. Rice. Eng. & Min. Jl., vol. 106, no. 12, Sept. 21, 1918, pp. 522-525, 4 figs. Detailed description of a car having a capacity of 82 cu. ft., to be let down a shaft 4 by 5 ft. and pass around a 28-ft. curve on a 24-in. track.

Safety Appliances

Safety in Winding Operations (II), J. A. Vaughan. South African Jl. & Eng. Rec., vol. 27, nos. 1400 and 1401, July 27, and Aug. 3, 1918, p. 318 and pp 296-297. July 27: Discussion of several faults or omissions of winding engine drivers, suggestions to prevent them. Aug. 3: Considerations on movement of reversing levers and automatic application of brakes. Before S. A. A. A. S. (Continuation of serial.)

Winding Mechanism

Automatic Cable Winding Mechanism, Donald A. Baker. Machy., vol. 25, no. 1, Sept. 1918, pp. 44-45, 3 figs. Arrangement for winding cable used for making lead balls for shrapnel shells.

Wire Ropes

The Factor of Safety of Wire Ropes (II). South African Mining Jl., vol. 27, part 2, no. 1394, June 15, 1918, pp. 171-172. Author's reply to criticisms of his previous discussion, offered by other members of the Inst. Paper before S. A. I. of E.

See also Railroad Engineering, Steam (Cranes); Safety Engineering (Winding Engines).

HYDRAULICS

Dams

Calaveras Dam Slide—Report on Failure of Hydraulic Fill Dam During Construction, D. C. Henny and C. H. Swigart. Reclamation Rec., vol. 9, no. 9, Sept. 1918, pp. 433-435, 2 figs. Report of investigation ordered by chief of construction, U. S. Reclamation Service, giving original construction, tests of materials and subsequent design amendments.

Method of Keying Sections of Concrete Dam, Frank P. Fifer. Can. Engr., vol. 35, no. 9, Aug. 29, 1918, p. 210, 1 fig. Method employed in construction of lock and dam on Hudson River at Troy, N. Y.

Sixty-One-Foot Hydraulic-Fill Dam Rests on Earth Foundation, William G. Fargo. Eng. News-Rec., vol. 81, no. 11, Sept. 12, 1918, pp. 491-495, 9 figs. Junction hydroelectric development in southern Michigan notable for winter placing of earth fill and for extreme height of concrete retaining walls, which hold 90 ft. of fill.

Weighing Materials Saved Cement on Three Big Dams, H. H. Hunt. Contract Record, vol. 32, no. 37, Sept. 11, 1918, pp. 738-740. How concrete proportioned by weighing the cement, sand and gravel reduced the volume of cement used on three hydroelectric developments completed recently in Michigan and Minnesota.

Hydroelectric Plants

New Hydroelectric Plant of Montana Power Company, W. A. Scott. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, pp. 18-22, 2 figs. Details of hydraulic equipment of project adding 48,000 kva. to system.

Mysore Irrigation Project

A Great Mysore Irrigation Project. The Waste Weir of the Krishnarajasagara, B. Bubba Rao. Indian & Eastern Engr., vol. 42, no. 5, May 1918, pp. 157-158, 2 figs. Program for completing war work; protection works; calculations for stability of waste weir section. Paper before Mysore Engrs.' Assn. (Continued from preceding issue.)

Tasmania Hydroelectric Development

The Great Lake Hydro-Electric Development of Tasmania, Ludwig W. Schmidt. Power, vol. 48, no. 10, Sept. 3, 1918, pp. 328-330, 7 figs. Description of some features of a 100,000-hp. hydroelectric development undertaken by private enterprise and completed with financial aid of government of Tasmania.

Water Power

Water Power Development to Conserve Coal. Ry. Rev., vol. 63, no. 8, Aug. 24, 1918, pp. 268-270. Outline of legislation proposed by administration to conserve country's fuel supply and man power through resort to hydroelectric development on an extensive scale for railway purposes.

Water Power in Industry: Its Place and Value, A. Newlands. Ry. News, vol. 110, no. 2854, Sept. 14, 1918, pp. 195-196. Estimated extent to which water power has been utilized the world over. (British Science Guild.)

Water Works

War Burdens of Water-Works in the United States, Am. City, vol. 19, no. 3, Sept. 1918, pp. 193-194. Summary of findings and conclusions of Executive Committee of Am. Water Works Assn.

Water Works Operation. Mun. Jl., vol. 45, no. 9, Aug. 31, 1918, pp. 170-171, 1 fig. Selection of service pipe—galvanized lead, lead-lined and cement-lined.

See also Air Machinery (Air Compressors); Sanitary Engineering (Water Supply).

INDUSTRIAL ORGANIZATION

Depreciation

Depreciation and Rate Making, L. R. Nash. Elec. Ry. Jl., vol. 52, no. 12, Sept. 21, 1918, pp. 511-513. States that use of an undepreciated value with sinking-fund accruals for depreciation is not only justified by precedent and correct accounting principles but is desirable on ground of public policy.

Industrial Census

What an Industrial Census Can Do, Dale Wolf. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 213-216. Results of an experiment of Miller Lock Co.

Industrial Organization

New Developments in Industrial Organization, W. G. Cass. Cassier's Eng. Monthly, vol. 54, no. 3, Sept. 1918, pp. 131-142. Methods followed at Port Sunlight Works. (To be continued.)

See also Marine Engineering (Industrial Management); Railroad Engineering, Steam (Salvage).

INTERNAL-COMBUSTION ENGINEERING

Alcohol Engines

Power-Alcohol and Alcohol Engines. Automobile Engr., vol. 8, no. 116, July 1918, pp. 188-189. Notes on report of Committee of Advisory Council of Science and Industry of Australia.

Diesel Engines

Coal Tar Oil for Diesel Engines, A. W. H. Griepe. Gas Eng., vol. 20, no. 10, Oct. 1918, pp. 465-473, 11 figs. Physical and chemical characteristics of suitable coal-tar oils.

Conserving Our Natural Resources by the More Extended Use of the Diesel Engine, P. L. Scott. Sibley Jl. of Eng., vol. 32, no. 12, Sept. 1918, pp. 178-180. Shows position author believes Diesel and surface-ignition engines will occupy in conservation of

present source and in use of fuels not yet widely recognized. From The Pacific Marine Review. (First of a series of six articles.)

Gas Turbines

The Gas Turbine, Georges Funck. Automobile Engr., vol. 8, no. 118, Sept. 1918, pp. 249-254, 20 figs. Two possible methods of operation of a steam turbine; illustrations of two proposed methods for gas turbine combustion of mixture at constant pressure, and at constant volume. Efficiency obtainable in gas turbine. Paper before Graduates' Section, Instn. Automobile Engrs.

High-Speed Engines

High Speed Internal Combustion Engines, H. R. Ricardo. Mech. World, vol. 64, no. 1648, Aug. 2, 1918, p. 57. Range of mixture strength available with petrol; volumetric efficiency. Paper before Northeast Coast Instn. of Engrs. & Shipbuilders. (Continuation of serial.) Also published in Automobile Engr., vol. 8, no. 116, July 1918, pp. 184-188, 18 figs.

Low-Compression Oil Engines

Some Features of Low Compression Oil Engines, L. H. Morrison. Power, vol. 48, no. 13, Sept. 24, 1918, pp. 455-458, 8 figs. Several forms of fuel injection pumps and nozzles described and information given concerning their care and repair. (Fifth article.)

Offset Cylinders

Offset Cylinders, A. Johnson. Automobile Engr., vol. 8, no. 118, Sept. 1918, pp. 244-245, 3 figs. Mathematical investigation of desaxe setting.

Rotary Engines

Augustine Rotary Two-Cycle Super-Induction Gas Engine. Gas Eng., vol. 20, no. 10, Oct. 1918, pp. 481-487, 14 figs. Description with drawings of new design of rotary air-cooled engine developed by Augustine Automatic Rotary Engine Co., Buffalo, N. Y.

Thermodynamic Cycles

Thermodynamic Cycles in Internal Combustion Engines, Wm. J. Walker. Aerial Age, vol. 8, no. 3, Sept. 30, 1918, pp. 126-127, 12 figs. Discussion of increasing power of engine by increasing m.e.p. of cycle.

Tractor Engines

Oil Burning Tractor Engines, H. H. Sward. Jl. Soc. Automotive Engrs., vol. 3, no. 3, Sept. 1918, pp. 209-210, and discussion 210-211. Considerations regarding fuel selection.

See also Aeronautics (Engines).

LABOR

Contract System

Labor Shortage Made Good by Station Contract System, F. P. Kemon. Eng. News-Rec., vol. 81, no. 12, Sept. 19, 1918, pp. 542-544, 4 figs. How Winnipeg aqueduct workers speeded completion of work at contract prices which netted 30 to 40 per cent increase in wages.

Coöperative Plants

Philadelphia Coöperative Plan Extended. Elec. Ry. Jl., vol. 52, no. 11, Sept. 14, 1918, pp. 459-462. Success of the plan for producing cordial relations between labor and capital demonstrated by eight years of experience; wages now raised to equal of the highest established by War Labor Board; several changes in original plan.

Solving Labor Relationship Problems. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 320-322. Account of work done by directors of a company who have asked their employees to coöperate with them and to help decide what their mutual relation should be. (To be continued.)

Cost of Living

How to Determine Cost of Living in an Industrial Community, Ray M. Hudson. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 185-192. Gives in complete detail results and basis of a cost study made for the H. H. Franklin Mfg. Co.

Cripples

Rehabilitating Cripples at Ford Plant, J. E. Mead. Iron Age, vol. 102, no. 13, Sept. 26, 1918, pp. 739-742, 8 figs. Full efficiency obtained by 85 per cent; light handwork in hospital speeds recovery.

Employee Representation

Midvale Plan of Employee Representation. Iron Age, vol. 102, no. 14, Oct. 3, 1918, pp. 834-835. Delegate for each 300; about one-tenth of these form plant committee; general committee for all plants; arbitration provided for if necessary.

Housing

Engineering Possibilities of Circular Housing Plan, G. J. Lamb. Can. Engr., vol. 35, no. 9, Aug. 29, 1918, pp. 193-196, 3 figs. Layout of block of 21 houses; particulars of water mains, sewers and maintenance.

Labor Plans

Beginnings of Labor Maintenance Service in a Small Plant, Mary L. Morris. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 205-208, 3 figs. How this work was started in a textile mill employing 500 workers; work divided into medical, employment and social divisions.

Conservation of Our Human Equipment, Earl B. Morgan. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 316-318. Methods of selecting men for job; organizing methods for taking care of workmen; how to conduct investigations; centralizing control of shop activities. (Concluded from June issue.)

How a Medium-Sized Plant Solves Its Labor Problems, H. E. Sloan. Machy., vol. 25, no. 1, Sept. 1918, pp. 11. Proper working conditions; hourly wages and bonus payments; American citizenship desirable.

Mine Labor

The Coal Shortage, F. W. Gray. Can. Min. Jl., vol. 39, no. 17, Sept. 1, 1918, pp. 291-293. True aspects of situation as seen by writer who suggests return of enlisted miners.

Training

Experience in Training Mechanical Operators. Iron Age, vol. 102, no. 10, Sept. 5, 1918, pp. 551-553, 8 figs. Machine-tool plant of medium size succeeds in effort to develop efficient workers from unskilled men and women.

How to Start Training in a Factory, Frank L. Glynn. Am. Industry, vol. 19, no. 2, Sept. 1918, pp. 22-25, 4 figs. Plan developed in Curtiss Aeroplane Co., Buffalo, and suggestions to manufacturers.

Industrial Training A War Measure, C. S. Coler. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 352-353, 4 figs. Vestibule school of Westinghouse Elec. and Mfg. Co.

Training Men and Boys in a Shop School, A. N. Hook. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 567-569. Successful methods of graduating a large number of workmen and at the same time lessening the financial burden of the school's maintenance.

Training School at Hog Island, W. H. Blood. Stone & Webster Jl., vol. 23, no. 3, Sept. 1918, pp. 178-181, 9 figs. System followed and results being obtained.

Turnover

Computing Labor Turnover. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 239-246. Results of a questionnaire to determine definition of labor turnover and how it is computed in various plants.

Wages

Living Costs and Wage Standardization, W. B. Wilson. Aera, vol. 7, no. 2, Sept. 1918, pp. 145-146. Secretary of Labor in New York address says differences as between communities may have to be disregarded and uniform rates provided for entire country.

New Wage Increase. Ry. Rev., vol. 63, no. 10, Sept. 7, 1918, pp. 335-339. Text of two supplements stabilizing wages and removing inequalities occurring in general order No. 27, United States Railroad Administration.

Women Workers

The Employment of Women in Munition Factories, O. E. Monkhouse. Jl. Instn. Mech. Engrs., no. 4, April 1918, pp. 213-221. Unskilled types of women educated, domestic, ordinary, training of women; how they have reached their present skill; hours of work.

Training the Woman War Worker, Edward K. Hammond. Machy., vol. 25, no. 1, Sept. 1918, pp. 15-17, 3 figs. Methods used in the plant of Taft-Pierce Company, Woonsocket, R. I., in training of women machine operators by means of a "vestibule" school.

Women on Kansas City Railways, J. E. Gibson. Aera, vol. 7, no. 2, Sept. 1918, pp. 93-102, 6 figs. What has been done to make their employment attractive and to secure the best class.

Women Substation Operators a Notable Success. Elec. World, vol. 72, no. 12, Sept. 21, 1918, pp. 545-548, 6 figs. Pioneer work of Boston Edison Co. in training women for electrical service; synopsis of course of instruction.

See also Foundry (Man Power); Marine Engineering (Man Power); Mines and Mining (Man Power).

LIGHTING

Daylight, Artificial

Artificial Daylight in the Industries, M. Luckiesh. Elec. World, vol. 72, no. 13, Sept. 28, 1918, pp. 596-598. Qualifications of light required for color discrimination, with examples of industrial use of daylight lamps installed in many varied establishments.

Factory Lighting

Laws Relating to Factory Lighting, W. T. Blackwell. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 312-313. Discussion on proper application of light in shops.

Some Important Phases of Industrial Lighting, W. T. Blackwell. Elec. Rev., vol. 73, no. 10, Sept. 7, 1918, pp. 360-362, 3 figs. Conservation of labor through improved lighting; proper lighting layout a simple problem; typical example; commonly neglected features of factory lighting.

Lighting Methods

The Lighting Art; Its Practice and Possibilities in Interiors. M. Luckiesh. Trans. Illuminating Eng. Soc., vol. 13, no. 6, Aug. 30, 1918, p. 354. Abstract of paper before Chicago Section of society.

Selection of Lighting Units, Davis H. Tuck. Elec. World, vol. 72, no. 12, Sept. 21, 1918, pp. 552-554, 5 figs. Simple method of analyzing distribution curves explained; efficiency of reflectors.

Paint Works

Improvement of Lighting of Paint and Varnish Works, F. H. Bernhard. Elec. Rev., vol. 73, no. 13, Sept. 28, 1918, pp. 481-486, 6 figs. Seventh article on improvement of lighting in the industries.

Woodworking Plants

Need of Improved Lighting of Woodworking Plants, F. H. Bernhard. Elec. Rev., vol. 73, no. 11, Sept. 14, 1918, pp. 401-408, 8 figs. Sixth of series of articles on lighting in the industries. Present article shows how better lighting speeds up production, improves quality and reduces accidents; low cost; common faults; some suggestions for betterment.

See also Electrical Engineering (Lighting); Municipal Engineering (Street Lighting); Railroad Engineering, Steam (Car Lighting).

LUBRICATION

Dredges and Shovels

Lubrication of Steam Shovels and Dredges. Eng. & Cement World, vol. 13, no. 5, Sept. 1, 1918, p. 74. Recommendation made by the Texas Co.

Lubricating Oils

Lubrication and Lubricating Oils, N. C. Brunn. Ry. Gaz., vol. 29, no. 8, Aug. 23, 1918, pp. 205-206. Abstract of results obtained on neutral, animal and vegetable oils. From paper before Soc. of Engrs., Tokio.

Viscosity

Relation Between Viscosity and the Chemical Constitution of Lubricating Oils, A. E. Dunstan and F. B. Thole. Jl. Instn. Petroleum Technologists, vol. 4, no. 16, June, 1918, pp. 191-216, 5 figs., and (discussion) pp. 216-229. Theoretical discussion on measurement of absolute viscosity; review of experimental data on American, Russian and Scotch oils, obtained by various authors; condensed bibliography.

See also Air Machinery (Air Compressors); Machine Shop (Oil Reclamation); Marine Engineering (Oil Coolers).

MACHINE DESIGN

Nomography

Nomography in Engine Design, F. Leigh Martineau. Jl. Soc. Automotive Engrs., vol. 3, no. 3, Sept. 1918, pp. 224-234, 23 figs. Practical study of graphic representation of formulæ and construction of various diagrams. Paper before Instn. Automotive Engrs., London.

MACHINE PARTS

Bearings

Ball Bearings for Machine Shop Equipment, Edward K. Hammond. Machy., vol. 25, no. 1, Sept. 1918, pp. 50-58, 22 figs. Second of a series.

Refitting Engine Bearings, C. H. Willey. Mech. World, vol. 64, no. 1648, Aug. 2, 1918.

pp. 56-57, 6 figs. Oil-flood method to locate knocks that develop during a run on a peak load; rebabbitting bearings. From National Engineer. (To be continued).

Using Ball Bearings in Marine Machinery. Can. Machy., vol. 20, no. 11, Sept. 12, 1918, pp. 322-323, 6 figs. Work done in Sweden; progress made in Canada.

Belts

Belting Problems Discussed at Chicago Meeting. Eng. & Cement World, vol. 13, no. 4, Aug. 15, 1918, pp. 56-60. Account of meeting of belt manufacturers, sales representatives and engineers at which data concerning belt performance in varied industrial plants were presented.

Bolts

Big End Bolts. Gas & Oil Power, vol. 13, no. 156, Sept. 5, 1918, pp. 173-174, 1 fig. Discussion of their fracture and failure.

Pulleys

Saving Coal by Efficient Pulleys, Charles H. Machen. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 536-538, 4 figs.

Springs

Helical Springs, M. H. Sabine. Mech. World, vol. 64, no. 1648, Aug. 2, 1918, p. 55, 6 figs. Layout and formulæ to determine number of coils and free length.

See also Aeronautics (Bolts); Forging (Piston Rods).

MACHINE SHOP

Balancing

Methods of Balancing Rotors, C. C. Brinton. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 349-352, 9 figs. Static and dynamic balancing systems and machines.

Bulldozer Operations

Bulldozer Operations with One and Two-Motion Dies, J. V. Hunter. Am. Mach., vol. 49, no. 11, Sept. 12, 1918, pp. 465-470, 20 figs. A variety of work that can be done in a bulldozer with properly designed dies.

Case-Hardening Materials

Case Hardening, S. S. Amdursky. Gas Industry, vol. 18, no. 8, Aug. 1918, pp. 259-261, 3 figs. Result of investigations by a gas and electric company into possibilities of converting both coal and oil-fired case-hardening furnaces to use gas.

Testing the Relative Merits of Case-Hardening Materials, Clarence N. Underwood. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 569-571, 3 figs. Method consists in case-hardening test pieces with various materials to be tested and in measuring the results.

Cutting Metals

The Cutting of Iron and Steel by Oxygen (XVIII), M. R. Amadeo (Translated from original French by D. Richardson). Acetylene & Welding Jl., vol. 15, no. 179, Aug. 1918, pp. 140-141, 1 fig. Peculiarities of carburized metal found in cuts made with central-jet blowpipes; formation of heating flame.

Gage Making

Elements of Gage Making, C. A. Macready. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 511-519, 21 figs. Amount and trend of distortion due to heating by grinding wheels. Fourth of series.

Heat Treatment

Correct Heat Treatment of Die Blocks, G. Peterson. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 295-297, 1 fig. Theory of crystallization and influence of mass in relation to temperature; bearing of these theories on subject.

Heat-Treating Gears for Army Trucks in the Electric Furnace, Dwight D. Miller. Am. Mach., vol. 49, no. 11, Sept. 12, 1918, p. 461, 1 fig. Benefits derived from proper heat treatment of gears; use of electric furnace for heat treatment of gears; use of electric furnace for heat treatment.

Using Electrical Furnaces for Annealing, Wirt S. Scott. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, p. 323. Control equipment used; conditions for which furnace is adapted. (Concluded from June issue.)

Milling

Milling Practice in Railway Shops, Frank A. Stanley. Ry. Mech. Eng., vol. 92, no. 9, Sept. 1918, pp. 521-524, 9 figs. Examples of cutters used with success in Southern Pacific Shops in Sacramento, Cal.

Navy Repairs

War-Time Repairs in the Navy, Frank A. Stanley. Am. Mach., vol. 49, no. 14, Oct. 3, 1918, pp. 621-624, 12 figs. Describes a miscellaneous line of work and special cutters, hobs and other tools. Fourth article.

Oil Reclamation

Reclaiming Oil from Metal Turnings, C. L. Smith. Iron Age, vol. 102, no. 10, Sept. 5, 1918, pp. 558-559, 3 figs. Scheme employed by Cincinnati Milling Machine Co. makes use of a special collecting truck and a separator set flush with floor.

Plating

Effecting War Economies in the Plating Room, E. P. Later. Foundry, vol. 46, no. 10, Oct. 1918, pp. 461-463. How waste may be eliminated and metals, acids and other materials conserved by exercising greater care in operation.

Radiator Manufacture

The Manufacture of the Sperry-Type Automobile Radiator. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 522-524, 8 figs. Description of the sheet-metal work in making this type of radiator.

Welding

The Autogenous Welding of Lead (III), P. Rosenberg. Acetylene & Welding Jl., vol. 15, no. 179, Aug. 1918, pp. 134-135, 8 figs. Hydrogen and oxy-acetylene installations.

Electric Arc Welding. Domestic Eng., no. 277, Sept. 1918, p. 5. Formula to calculate approximate heat quantities involved in welding. Paper before Cleveland Eng. Soc.

Fusion Welding Fallacies, S. W. Miller. Machy., vol. 25, no. 1, Sept. 1918, pp. 12-13, 5 figs. Third of a series.

Selection and Application of Electric Arc Welding Apparatus, A. M. Candy. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 337-346, 25 figs. Chief requisites for electric arc welding both with alternating and direct current; constant-current vs. constant-potential generators; protective equipment and accessories; selection of electrodes; gas vs. arc.

Wheel Hubs

Machining Front Wheel Hubs, A. Thomas. Automobile Engr., vol. 8, no. 118, Sept. 1918, pp. 264-266, 12 figs. Operations in manufacturing front-wheel hub from drop forging of 3 per cent nickel steel.

See also Air Machinery (Compressed-Air Applications); Marine Engineering (Welded Ships); Mechanics (Balancing); Millwrighting; Safety Engineering (Machinery Movements).

MACHINE TOOLS

Dies

Construction and Operation of Temporary Dies, Hugo F. Pusep. Am. Machy., vol. 49, no. 11, Sept. 12, 1918, pp. 488-489, 6 figs. Method outlined shows how dies can be built for small output at little expense.

Double-Movement Dies for Bulldozer Work, J. V. Hunter. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 508-510, 9 figs. Illustrations of cheaply made double-movement dies for use in a bulldozer

Presses

Dies for Tape-Measure Winder. Machy., vol. 25, no. 1, Sept. 1918, pp. 46-48, 6 figs. Set of dies for performing sequence of operations under power press.

Mechanical Presses, Métanx, Alliages et Machines, year 11, no. 7, July 1918, pp. 10-13, 9 figs. Their utilization after the war. (Concluded from May issne.)

Wright Dieing Machine. Machy., vol. 25, no. 1, Sept. 1918, pp. 73-75, 3 figs. Machine adapted for performance of those classes of operations usnally handled in dies operated by power presses.

See also Metal-Working Tools

MACHINERY, SPECIAL

Hosiery Machinery

Drilling Jigs Used in the Manufacture of Hosiery Machines, Robert Mawson. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 563-565, 10 figs. Many of the jigs described are simple in design but produce as equally accurate results as more complicated tools.

Sand-Blast Machinery

Automatic Positive Pressure Sand Blast Apparatus. Compressed Air Mag., vol. 23, no. 9, Sept. 1918, pp. 8884-8886, 1 fig. Machine controlled by specially designed manifold valve.

MARINE ENGINEERING

Barges

Upper Mississippi River Barge Fleet, B. L. Brown. Jl. Engrs. Club of St. Louis, vol. 3, no. 4, July-Aug. 1918, pp. 199-202. Data on construction and equipment of 19 steel barges, with double bottoms and four towing steamers, designed to handle up-stream tonnage against rapid currents.

Cargo Steamers

The Most Suitable Sizes and Speeds for General Cargo Steamers, John Anderson. Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 505-511, 13 figs. Method of determining most economical dimensions of cargo vessels for any length of voyage, condition of loading and speed. Paper before Instn. of Naval Architects, London, March 1918.

Concrete Ships

Concrete Barge Specifications Show Many Unusual Features. Marine News, vol. 5, no. 3, Aug. 1918, pp. 70-71 and 122. Details of 21 vessels to be used on New York state barge canal system.

Concrete Ships, Harvey S. Owen. Jl. Engrs. Club of St. Louis, vol. 3, no. 4, July-Aug. 1918, pp. 243-255. Concrete ship designing problems; light aggregate and protective coating recently developed; opinions regarding durability of concrete ships.

Construction Features of Concrete Ships. Eng. & Contracting, vol. 50, no. 13, Sept. 25, 1918, pp. 303-304. The concrete; reinforcing steel; mixing and placing concrete; durability of a concrete ship. Abstract of paper by Rudolph J. Wig and S. C. Hollister before Amer. Concrete Inst.

Construction of Concrete Ships for Emergency Fleet Corporation, R. J. Wig. Can. Engr., vol. 35, no. 9, Aug. 29, 1918, pp. 212 and 214. Principal characteristics of 3500-ton concrete ship. From special report to U. S. Shipping Board.

Developments in Concrete Barges and Ships, J. E. Freeman. Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 520-522. Brief résumé of history of concrete shipbuilding; what has been accomplished in United States and abroad. From paper before Am. Concrete Inst., June 1918.

Ferro-Concrete Ships. Ferro-Concrete, vol. 10, no. 1, July 1918, pp. 7-17. Discussion of paper by T. J. Gueritte before North-East Coast Instn. of Engrs. & Shipbuilders, published in Apr. issue.

Method of Concrete Ship Construction, Theodore Ahlborn. Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 517-520, 6 figs. Reinforcing diagrams of parts of the hull; methods of construction.

Reinforced Concrete Vessels, Walter Pollock. Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 512-517, 9 figs. Discussion of factors involved in designing small coastwise concrete motorship. From paper before Instn. of Naval Architects, London, March 1918.

Eagles

Manufacturing Eagles at Ford Shipyard, Chas. Lundberg. Iron Age, vol. 102, no. 12, Sept. 19, 1918, pp. 679-684, 13 figs. Submarine chasers assembled on wheels and dropped into water; a launching a day the aim; general description of operation and plant.

Electrical Machinery

Electrical Applications to Merchant Vessels, H. A. Hornor. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 490-503. General methods of installation in present practice; distribution, generating sets, switchboards, lighting fixtures, searchlights and interior communication.

Fabricated Ships

Assembling and Regulating Ship's Structure, T. L. Cohee. Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 534-536. Rigid supervision and strict check and recheck system necessary to eliminate errors in assembling fabricated ships.

Control of Hull Construction of 5000-Ton Deadweight Fabricated Steel Vessel, "Fabricator." Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 536-538. System employed at yard where straight work was produced at outside shops and furnaced work turned out at yard.

Industrial Management

Putting Our Merchant Ships on Schedule, L. P. Alford. Indus. Management, vol. 56, no. 3, Sept. 1918, pp. 227-230, 7 figs. How principles of industrial management have been applied in controlling ship movements.

Man Power

Manning the New Merchant Marine, Henry Howard. Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 499-501. Free schools established for training deck and engine-room

crews for American ships; details of system explained.

Training Workers for Wooden Shipyards. Int. Mar. Eng., vol. 23, no. 9, Sept. 1918, pp. 526-528, 4 figs. New course of instruction organized at Pratt Institute, Brooklyn, N. Y., for woodworkers in shipyards.

Oil Coolers

Multiwhirl Oil Cooler. Power, vol. 48, no. 14, Oct. 1, 1918, p. 489, 2 figs. Description of a watercooled oil-cooler through which oil to be cooled is pumped in a helical path so as to strike the water-filled tubes at right angles.

Passenger Steamers

Twin Screw Passenger Steamer "Stavangerfjord." Engineering, vol. 106, no. 2746, Aug. 16, 1918, pp. 170-172, 21 figs. Deck plans, elevation, photographs and detailed description of features of the new 13,000-ton steamer built by Cammell, Laird & Co., Ltd., Birkenhead.

Shallow-Water Boats

Solving the Shallow Water Problem, W. V. Kidder. Motor Boat, vol. 15, no. 18, Sept. 25, 1918, pp. 13-14, 4 figs. Boat with flat "shovel" nose set in motion by air propeller in stern.

Standard Vessels

Further German Views on Standard Cargo Vessels, E. Goos. Shipbuilding & Shipping Rec., vol. 12, no. 10, Sept. 5, 1918, pp. 231-232, 1 fig. Considers that German yards, with possible exception of new yards recently built, have little to gain and much to lose by adopting policy of standard shipbuilding. From Schiffbau (Hamburg).

Welded Ships

Electrically Welded Cargo Ships. Jl. Engrs. Club of St. Louis, vol. 3, no. 4, July-Aug. 1918, pp. 203-210. Review of problems of welding in their application to marine construction and of work being done by U. S. Shipping Board, Emergency Fleet Corporation. From Nauticus.

Evolution of Electric Welding Processes as Applied to Shipbuilding, H. A. Hornor. Jl. Engrs. Club of St. Louis, vol. 3, no. 4, July-Aug. 1918, pp. 256-263. Electric welding in railway shops; application to steel shipbuilding; British Admiralty investigation; experiments under way in the U. S.; electric welding methods. From Nauticus (special supplement).

Application of Electric Welding to Shipbuilding. Engineering, vol. 106, no. 2747, Aug. 23, 1918, pp. 197-199. Results of a six-months' series of tests and experiments carried out by Lloyd's. Also published in Shipbuilding & Shipping Rec., vol. 12, no. 8, Aug. 22, 1918, pp. 186-188.

Electric Welding as Applied to Steel Ship Construction. Eng. & Contracting, vol. 50, no. 13, Sept. 25, 1918, pp. 308-309. Description of work of Electric Welding Committee of Emergency Fleet Corporation. General features of steamer; type of joints; method of assembly; amount of welding required. Also published in Jl. Engrs. Club of Phila., vol. 35-39, no. 166, Sept. 1918, pp. 427-428, and discussion pp. 428-439, 16 figs.

Welding

The Application of Electric Welding to Ship Construction and Repair. Elecn., vol. 81, no. 2102, Aug. 30, 1918, p. 379. A résumé of present practice.

See also Machine Shop (Navy Repairs); Mechanics (Specific Speed Method).

METAL-WORKING TOOLS

Boring Machines

Defiance No. 5, Horizontal Boring, Milling, Drilling and Tapping Machine. Am. Mach., vol. 49, no. 11, Sept. 12, 1918, pp. 499-500, 1 fig. Description, with principal dimensions.

Overhead Flexible Boring Machine. Ry. Gaz., vol. 29, no. 6, Aug. 9, 1918, p. 160, 2 figs. Illustration of machine designed to meet demand for means of applying the Russell patent screwdriver to pieces of work which cannot be handled under spindle of an ordinary fixed drilling press. Also published in Practical Engr., vol. 58, no. 1640, Aug. 1, 1918, p. 51, 2 figs.

Gear-Cutting Machinery

The Works of the Moss Gear Co. Automobile Engr., vol. 8, no. 116, July 1918, pp. 203-210, 22 figs. Machines used and employed in factory specializing in manufacture of toothed gearing.

Millers

The Kempsmith "Maximiller." Am. Mach., vol. 49, no. 14, Oct. 3, 1918, pp. 595-600, 8 figs. Description of all-geared milling machine built by Kempsmith Mfg. Co., Milwaukee, Wis.

Milling Cutters

Grinding Relief of Milling Cutters. Machy., vol. 25, no. 1, Sept. 1918, pp. 9-10, 7 figs. Comparison of use of disk wheels and cup wheels for grinding milling cutters and an analysis of results obtained.

Nut-Forging Machine

Hollings Indenting Type of Nut-Forging Machine. Machy., vol. 25, no. 1, Sept. 1918, pp. 33-35, 5 figs. Machine which in conjunction with the special bar stock used makes it possible to produce well-formed blanks without excessive pressure and with a relatively small amount of scrap.

Pitch-Measuring Machine

Pitch Measuring Machine for Screw Gauges. Can. Machy., vol. 20, no. 11, Sept. 12, 1918, pp. 320-321, 2 figs. Features of Bingham Powell type.

Shell-Boring Lathe

"Galloway" Shell-Boring Lathe. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 544-545, 1 fig. Illustration and principal dimensions.

Taps and Dies

Taps and Dies for Production Work, G. Doorakkers. Engineer, vol. 126, nos. 3269 and 3270, Aug. 23 and Aug. 30, 1918, pp. 151-152 and 186-187, 1 fig. (first and second articles), 5 figs.

Wrigglers

Wrigglers and Their Uses, Hugo F. Pusep. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 559-560, 5 figs. Use of wrigglers in locating points on work to be drilled or milled when a fairly liberal tolerance is allowed.

See also Machine Tools.

MECHANICS

Balancing

The Balancing of Heavy Rotors, M. W. Torbet. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 518-533, 6 figs. Mathematical discussion of forces and couples based on six typical equations of motion.

Beams, Offset

The Design of Offset Beams, Victor M. Summa. Ry. Mech. Eng., vol. 92, no. 9, Sept. 1918, pp. 514-517, 9 figs. Discussion of formulæ used.

Rotation, Rapid

On the Determination of the Resistance to Motion of Rapidly Rotating Machines (Om bestämmande af wastigt roterande maskiners rörelsemotstand), Erik Aug. Fursberg. Teknisk Tidskrift, vol. 48, no. 31, Aug. 3, 1918, pp. 385-389. (To be continued.)

Specific-Speed Method

Design of Water Propellers by the Specific Speed Method, Chas. F. Gross. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 534-546, 5 figs. Presents to draftsmen method of propeller design when given power propeller is to absorb and the speed of advance of propeller through water, items to be determined being diameter, pitch, mean width ratio and blade thickness.

Speed, Critical

Critical Speed in Tapered Shaft Design, Alfred Musso. Machy., vol. 25, no. 1, Sept. 1918, pp. 59-60, 1 fig. Derivation of formulæ and examples illustrating their use.

See also Railroad Engineering, Steam (Shocks in Trains).

METAL ORES

Chromite

Chromite, J. C. Williams. Colo. School of Mines, vol. 8, no. 9, Sept. 1918, pp. 157-159. Foreign and domestic deposits; uses of chromium; alloys; description of chromite; its occurrence and concentration.

Manganese

Manganese Deposits of East Tennessee. The Resources of Tennessee, vol. 8, no. 3, July 1918, pp. 153-207, 10 figs. Report of results of field work by geologists of U. S. Geol. Survey in coöperation with the State Geol. Survey of Tennessee; geography of region; manganese minerals; rocks with which ore is associated; types of deposits; description of typical mines and prospects.

Pyrolusite from Virginia, Thomas L. Watson and Edgar T. Wherry. Jl. Wash. Acad. of Sci., vol. 8, no. 16, Oct. 4, 1918, pp. 550-560, 1 fig. Geology of manganese deposits and crystallography of ore.

Tungsten

Molybdenum, Tungsten and Bismuth. Ind. Australian & Min. Standard, vol. 60, nos. 1552, 1553, 1554, Aug. 8, 15 and 22, pp. 210-211, 245-247, and 284. Treatise on these minerals. Aug. 8: Molybdenite occurrences in Northern Europe, South America, and South Africa; geographical distribution of wulfenite. Aug. 15: list of wulfenite occurrences in United States. Aug. 22: occurrences of wulfenite in Central and Southern Europe, and Australasia.

See also Steel and Iron (Iron-Titanium Ores), (Ore Resources).

METALLURGY

Aircraft

The Metallurgist and the Aircraft Program (III), H. F. Wood. Am. Drop Forger, vol. 4, no. 8, Aug. 1918, pp. 318-319. Suggestions on selection and testing of engine parts; responsibility of metallurgist on success of an airplane engine. From paper before Steel Treating Research Soc.

Tin

The Taylor Concentrator for Tin Slime, J. Waring Partington. Queensland Government Min. Jl. vol. 19, no. 219, Aug. 15, 1918, pp. 352-353 and 359-360, 3 figs. Consists of 24 rectangular concentrating surfaces attached to, and revolving with, a central vertical shaft, the latter being provided at its upper extremity with a worm gearing by means of which motion is imparted to frame. Machine designed in effort to eliminate disadvantages of usual type of revolving wooden round frame.

Wastes

Recuperation and Utilization of Wastes in the Manufacture of Copper, Zinc, Lead, Tin, Aluminum and Their Alloys (La récupération et l'utilisation des déchets de cuivre, zinc, plomb, étain, aluminum et de leurs alliages), Paul Razons. Génie Civil, vol. 73, nos. 9 and 10, Aug. 31 and Sept. 7, 1918, pp. 171-174, 8 figs., and pp. 184-188, 1 fig. Aug. 31: Apparatus for recuperating copper vapors in copper works; method of washing copper filings. Sept. 7: usage of copper waste in the manufacture of cupric sulphate; remelting of bronze filings; by-products of zinc works and recuperation of zinc from refuse of galvanized iron. (To be continued.)

Zinc

Electrothermal Metallurgy of Zinc (La métallurgie électrothermique du zinc), J. Escard. Génie Civil, vol. 73, nos. 7, 8 and 9, Aug. 17, 24 and 31, 1918, pp. 124-127, 3 figs., pp. 141-146, 9 figs., and pp. 168-171, 5 figs. Aug. 17: Coal-reduction methods, De Laval and Johnson furnaces. Aug. 24: Condensation of zinc vapors; decomposition of zinc sulphide by iron; industrial furnaces. Aug. 31: Results obtained with Côte and Pierron furnaces; Peterson's process; Thomson-Gerald furnace; Snyder furnace.

MILLWRIGHTING

Belt Clearances

Belt Clearances for Oblique Drives, F. R. Parsons. Nat. Engr., vol. 22, no. 9, Sept. 1918, pp. 419-420, 3 figs. Description of setting out floor clearances and difficulties encountered; hints on how to do such work correctly. From Mech. World.

Shafting

Aligning and Erecting Shafting (I). Ironmonger, vol. 164, no. 2338, Sept. 7, 1918, p. 42, 4 figs. Supplementing information in series on belt-driving practice published June 29, July 6, and Aug. 10.

MILITARY ENGINEERING

Artillery

Calculation of a Long Range Gun (Note sur le calcul d'un canon à longue portée). Génie Civil, vol. 73, no. 10, Sept. 7, 1918, pp. 191-192, 1 fig. Calculation of characteristics of trajectory for 100 km. range; mechanical requirements of projectile.

Contract Organization

Contract Organization Vitally Important for War Work, Francis Donaldson. Eng. News-Rec., vol. 81, no. 12, Sept. 19, 1918, pp. 535-538. Large-scale government construction demands most careful coördination of forces; charts setting forth organization of two typical contracts.

Electrical Machinery

Electrical Developments for American Army, R. K. Tomlin, Jr. Elec. World, vol. 72, no. 12, Sept. 21, 1918, pp. 532-536, 8 figs. Present plans for troops in France provide for 50,000 kw.; technical board controls supplies and coördinates work of design

and construction; electrical machinery difficult to get.

Mine Safety Appliances

Mine Safety Appliances in Warfare. F. H. Trego. Coal Age, vol. 14, no. 11, Sept. 12, 1918, pp. 504-505. Account of mine safety appliances which have been adapted by War Department for use in war.

Railways, Military

Operation of the U. S. Military Railways in France, J. G. Porter. Ry. Age, vol. 65, no. 12, Sept. 20, 1918, pp. 549-551. How Americans adapted themselves to new transportation conditions encountered overseas.

Rifles

Temporary Small-Arms Repair Shop in France, R. K. Tomlin, Jr. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 535-536, 3 figs. Description of repair shop for salvaging rifles.

The Science of the Rifle, F. H. Kelly. Arms & Explosives, vol. 26, no. 312, Sept. 2, 1918, pp. 117-120, 2 figs. Action of bolt magazine and trigger parts. From writer's book under same title.

Sanitary Engineering

Water Supply Fire Protection, Roads and Waste Disposal of a Large Training Camp, Murray Warner. Am. City, vol. 19, no. 3, Sept. 1918, pp. 174-176, 1 fig. Distribution system of water supply based on standard daily allowance of 55 gal. per man; machines used in the five fire stations; sewage and garbage disposal.

Small Arms

Revolvers and Automatic Pistols (Les revolvers et les pistolets automatiques), L. Cabanès. Génie Civil, vol. 73, nos. 8 and 9, Aug. 24 and 31, 1918, pp. 146-150, 7 figs., and pp. 165-167. Aug. 24: English Gabbett-Fairfax model; American Colt 38: characteristics of Colt 45. Aug. 31: Classification of various types in order of merit; choice of pocket pistol for personal defense in peace times; choice for war service; automatic Colt 45.

Substations

The Outdoor Substation in War Service, E. B. Meyer. Elec. World, vol. 72, no. 12, Sept. 21, 1918, pp. 537-541, 9 figs. Through its use the sudden demand for power to supply war industries has been promptly met with a resulting conservation of material and labor.

Supply Bases

Army Intermediate Depot in France Problem in Getting Labor and Supplies, Robert K. Tomlin, Jr. Eng. News-Rec., vol. 81, no. 11, Sept. 12, 1918, pp. 478-483, 11 figs. Project covers site six miles long; three types of warehouses being built; Chinese labor used on railroad grading; installation completed for storing 5000 tons of beef at zero temperature.

Boston Army Supply Base Will Be Valuable Permanent Port Terminal. Eng. News-Rec., vol. 81, no. 12, Sept. 19, 1918, pp. 522-526, 5 figs. Description of storage warehouse in Boston having 60 acres of storage space.

Troop Transportation

A Novel Scheme for Carrying Troops by Rail, Frederick C. Coleman. Ry. Age, vol. 65, no. 11, Sept. 13, 1918, pp. 509-511, 5 figs. The Great India Peninsula Railway of India's military cars, holding 66 soldiers each, described.

Military Trains in India. Ry. Gaz., vol. 29, no. 9, Aug. 30, 1918, pp. 232-236, 13 figs. Plans and interior arrangement of carriages.

See also Mines and Mining (Explosives); Munitions.

MINES AND MINING

Asphalt

Asphalt Deposits and Oil Conditions in Southwestern Arkansas, Hugh D. Miser and A. H. Purdue. U. S. Geol. Survey, Bul. 691-J, Contributions to Economic Geology Part II, Aug. 16, 1918, pp. 271-292, 1 fig. Geography and geology; general features and local details of asphalt deposits; drilling for oil; well records.

Blackdamp

Outbursts of Gas in Crowsnest Field, James Ashworth. Coal Age, vol. 14, no. 10, Sept. 5, 1918, pp. 443-446, 3 figs. Description of violent gas outbursts which have caused coal fields to be shut down; theories advanced to account for outbursts; suggestions for proceeding with work. Abstract of pamphlet entitled Outbursts of Explosive Gases in the Crowsnest Pass Coalfield, British Columbia.

The Origin of Blackdamp, J. I. Graham. Trans. Instn. Min. Engrs., vol. 55, part 4, Aug.-Sept. 1918, pp. 303-312. Experiments from which author formulates four ordinary compositions of blackdamp resulting from different contributory causes.

Briquetting of Ores

Briquetting of Powdery Ores and of Blast Furnace Dust (Le briquetage des minerals pulvérulents et des poussières de hauts fourneaux). Génie Civil, vol. 73, no. 7, Aug. 17, 1918, pp. 131-134, 10 figs. Schumacher process; Fawcet, Sutcliffe and Speakman presses; nodulation and agglomeration processes.

Cementation

The François Cementation Process, A. H. Krynauw. Min. Mag., vol. 19, no. 2, Aug. 1918, pp. 68-77, 10 figs. Cases in which cement grout under pressure has been successfully applied and manner in which this has been done. From paper before Chem., Metallurgical, and Min. Soc. of So. Africa.

Explosives

Some Notes on Experiments Made with a View to Reducing the Consumption of Explosives, and Increasing the Fathoms Broken per Machine Shift in Machine Stoping, T. H. Bayldon. Jl. So. African Instn. Engrs., vol. 16, no. 12, July 1918, pp. 226-233, 2 figs. Tables comparing two methods: (1) drilling alternately on two stope faces and doubling size of benches, (2) cutting four three-hole benches for each machine on each face.

Man Power

Mechanical Equipment and the Conservation of Miners, R. L. Herrick. Compressed Air Mag., vol. 23, no. 9, Sept. 1918, pp. 8876-8881, 7 figs. Typical examples of man-power savings observed by writer on a 450-mile automobile trip about the mines in the anthracite district.

Salt

Salt Mining and Dressing, J. B. Calkins. Eng. & Min. Jl., vol. 106, no. 10, Sept. 7, 1918, pp. 431-435, 7 figs. Brief history of salt industry, with detailed account of mining and milling operations at a property in New York State having an output of 2000 tons of prepared salt in a 10-hr. day; details as to haulage, dressing and mechanical treatment.

Shale Oil

The Extraction of Oils from Shales and Coal. Petroleum Rev., vol. 39, no. 836, July 27, 1918, p. 59. New English patented process consisting in mixing powdered shale or coal both with some finely ground material (such as limestone, dolomite, carbonate of magnesium or barium carbonate), which, under the action of heat, will give off carbonic acid gas, and with small iron scrap (such as iron turnings) or its chemical equivalent for the purpose of causing the release of increased quantities of hydrogen.

See also Safety Engineering (Mine Accidents).

MOTOR-CAR ENGINEERING

Chassis

Military Transport Chassis (VII). Automobile Engr., vol. 8, no. 118, Sept. 1918, pp. 267-270, 4 figs. Details of F. W. D. (Model B) 3-ton chassis.

Fuels

The Valuation of Motor Fuels, Harold Moore. Automobile Engr., vol. 8, no. 118, Sept. 1918, pp. 245-248. Relative value of tests: specific gravity, viscosity, cold test, coke test, fractional distillation, specific heat, iodine and bromine values, ultimate analysis, temperature of spontaneous ignition, explosive range, calorific power.

Use of Gas for Automobiles. Gas Age, vol. 42, no. 5, Sept. 2, 1918, pp. 199-200. French discussion upon intensive trials both in England and France made with automobiles driven with illuminating gas.

Gear Changing

A Mechanism for Changing Gears Automatically. Automotive Ind., vol. 39, no. 10, Sept. 5, 1918, pp. 416-417, 4 figs. Gears shifted and clutch operated by engine power.

The Problem of the Gear Box. Auto, vol. 23, no. 35, Aug. 30, 1918, pp. 625-626. Inquiry of conditions limiting possibilities in design. (To be continued.)

Racing Cars

The 300 H.P. Fiat Racer. Autocar, vol. 41, no. 1189, Aug. 3, 1918, pp. 117-118, 1 fig. Dimensions and history.

Spark Plugs

How Automobile Spark Plugs Are Made. Commercial America, vol. 15, no. 3, Sept. 1918, pp. 33-37, 7 figs. Cold-drawing and automatic machine process; making porcelain; experimenting; testing and assembling.

Steering

Problems in Steering of Motor Cars Discussed from the Point of View of Projective Geometry (Anwendung eines Satzes der projektiven Geometrie auf die Lenkung von Automobilen), C. Veithen. Dingler's Polytechnisches Journal, vol. 333, no. 2, Jan. 26, 1918, pp. 9-10, 3 figs.

Three-Wheel Cars

The Morgan Runabout. Autocar, vol. 41, no. 1189, Aug. 3, 1918, pp. 123-124, 4 figs. Brief description of a three-wheeled light car.

Trailers

Development of the Trailer. Sibley Jl. of Eng., vol. 32, no. 12, Sept. 1918, pp. 180-185, 2 figs. Experimental basic trailing laws; steering.

Valve Design

Four Valves Per Cylinder. Autocar, vol. 41, no. 1195, Sept. 14, 1918, p. 264. Six-cylinder Pierce-Arrow engine with 12 inlet and 12 exhaust valves in side pockets.

See also Internal-Combustion Engineering; Machine Shop (Radiator Manufacture), (Wheel Hubs); Safety Engineering (Headlights, Automobile).

MUNICIPAL ENGINEERING

Catch-Basin Cleaning

Catch-Basin Cleaning in Chicago. Mun. Jl., vol. 45, no. 11, Sept. 14, 1918, pp. 199-200. Itemized costs of work done by hand and by auto-eductor, time of cleaning different basins.

City Planning

The Planning of the New Halifax, Thos. Adams. Contract Rec., vol. 32, no. 35, Aug. 28, 1918, pp. 680-683, 3 figs. Plans and details of six schemes, two for city and four for county.

The St. Louis Zone Plan, Harland Bartholomew. Jl. Engrs. Club of St. Louis, vol. 3, no. 4, July-Aug. 1918, pp. 214-240, 5 figs. Provisions of city building zone plan passed by Board of Aldermen.

Salvage

Municipal Salvage, J. C. Dawes. Surveyor, vol. 54, no. 1390, Sept. 6, 1918, pp. 111-112. Possibilities of utilizing ordinary house refuse. Inst. of Cleansing Superintendents. (To be concluded.)

Street Lighting

The Aesthetics of Street Lighting, M. Luckiesh. Trans. Illuminating Eng. Soc., vol. 13, no. 6, Aug. 30, 1918, pp. 355-356. Abstract of paper before Phila. Section of the Soc.

MUNITIONS

Canada

Canada's Production of Munitions of War. Can. Min. Jl., vol. 39, no. 17, Sept. 1, 1918, pp. 295-296. Summary of work of Imperial Munitions Board, with a few details regarding most important departments.

Explosives

Sengite: A New Explosive, J. P. Udal. South African Min. Jl., vol. 27, part 2, no. 1401, Aug. 3, 1918, p. 307. Process of manufacturing explosive made of gun coton impregnated with nitrate of soda.

Fuses

Making the Mark III Detonating Fuse. Edward K. Hammond. Machy., vol. 25, no. 1, Sept. 1918, pp. 27-32, 9 figs. First of a series describing operations involved.

Guns

Lathes for the Present Gun Program, A. L. De Leeuw. Am. Mach., vol. 49, no. 11, Sept. 12, 1918, pp. 491-493. Suggestions for obtaining at once required lathes for manufacture of guns.

The British 6-Inch Howitzer, I. W. Chubb. Am. Mach., vol. 49, no. 14, Oct. 3, 1918, pp. 605-612, 16 figs. Body and breach mechanism; various turning, boring, rifling and planing operations are described. (Third article.)

Helmets

Ancient Helmet Making, H. H. Manchester. Am. Mach., vol. 49, no. 12, Sept. 19,

1918, pp. 503-507, 28 figs. A résumé of art of making helmets from earliest times.

Machine Guns

The Manufacture of the Lewis Machine Gun Frank A. Stanley. Am. Mach., vol. 49, no. 12, Sept. 19, 1918, pp. 529-531, 9 figs. Thirteenth article describing manufacture of Lewis machine fun. Second article on the barrel, describing chambering, lapping and inspection.

Shells

Government Requires Millions of Gas Shells. Foundry, vol. 46, no. 10, Oct. 1918, pp. 441-442. Program of Government for next twelve months.

Rectifying Rough Bored 155-mm. Shells, M. P. Potter. Can. Machy., vol. 20, no. 9, Sept. 5, 1918, p. 297, 5 figs. Type of head developed after Government requirements.

Making the U. S. 8-in. Shell, M. E. Hoag. Am. Mach., vol. 49, nos. 11 and 12, Sept. 12 and 19, 1918, 9 figs, and 457-460, 11 figs. Describes turning and boring. (Serial.)

Labor-Saving Washing Device Used on Shell Work, J. H. Rodgers. Can. Machy., vol. 20, no. 9, Sept. 5, 1918, p. 299. Arrangement by which shells are subjected to a spray wash of soda solution, followed by a rinsing with clear hot water.

See also Military Engineering (Rifles), (Small Arms).

PHYSICS

Air

Physics of the Air, W. J. Humphreys. Jl. Franklin Inst., vol. 186, no. 3, Sept. 1918, pp. 341-370, 6 figs. Discussion of crushing of hollow conductors by lightning discharges; quantity of electricity in discharge; general rules for construction of an efficient system of lightning protection; electrical field of the earth; electrical conductivity of the atmosphere; ionic content of the air. (Continuation of serial.)

Luminous Materials

On the Luminescence Due to Radio-Activity, Enoch Karrer and D. H. Kabakjian. Jl. Franklin Inst., vol. 186, no. 3, Sept. 1918, pp. 317-340, 17 figs. Quantitative data on rejuvenation of self-luminous materials, and in particular of radium bromide.

PIPE

Corrosion Prevention

The Deactivator System for Elimination of Corrosion in Hot Water Supply Pipes. Eng. & Contracting, vol. 50, no. 13, Sept. 25, 1918, pp. 297-299, 1 fig. Description of an experimental plant installed in an apartment house in Boston and results obtained. Installation made by Research Laboratory of Applied Chemistry, Massachusetts Institute of Technology in coöperation with Research Department of National Tube Co.

Discussion Concerning the Destruction of Gas and Water Piping in Clayey Soils Containing Gypsum (Zur Zerstörung der Gas- und Wasserleitungen in gipshaltigem Lehmboden), P. Medinger. Journal für Gasbeleuchtung year 61, nos. 7 and 8, Feb. 16 and 23, 1918, pp. 73-76, 1 fig., and pp. 89-91, 3 figs. Extensive discussion of the underlying chemical phenomena.

Wood

Redwood Pipe and Its Uses. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, p. 32, 1 fig. Processes of making three principal types in present use.

See also Wood (Pipes).

POWER GENERATION AND SELECTION

Coal Mining

Electricity in Coal-Mining Operations, Frank Huskinson. Elec. World, vol. 73, no. 13, Sept. 28, 1918, pp. 494-495. Mine signaling and telephone systems; data on rope haulage; miscellaneous applications.

The Electrification of a Durham Colliery. Engineer, vol. 126, no. 3268, Aug. 16, 1918, pp. 136-138, 4 figs. Description of electrical equipment of a British colliery.

Combined Power

Economic Proportion of Hydroelectric and Steam Power, Frank G. Baum. Elec. Rev., vol. 73, no. 12, Sept. 21, 1918, pp. 450-451, 2 figs. New method of determining economical proportion of hydroelectric to steam power. From paper before Am. Inst. of Elec. Engrs.

Efficiency

Efficiency in Power Production, M. T. Berja. Aera, vol. 7, no. 2, Sept. 1918, pp. 175-177, and (discussion) pp. 177-178. Suggestions to engineers. (Manila Elec. Ry. & Light Co.)

Electricity

Industrial Applications of Electricity, Dwight D. Miller. Elec. Contractor-Dealer, vol. 17, no. 12, Oct. 1918, pp. 123-128, 2 figs. Examples of uses of electric heat; advantages of electric drive-friction losses, greater output for a given time, flexibility of operation, lighter building construction, safety.

Exhaust Steam

Utilization of Exhaust Steam in Collieries for the Production of Electrical Energy. (Considérations sur l'utilisation des vapeurs déchappement dans les houillères en vue de la production d'énergie électrique), A. Barjou. L'Industrie Electrique, year 27, no. 628, Aug. 25, 1918, pp. 308-312, 5 figs. Diagram and formula to determine steam consumption of low-pressure turbines; scheme of connections for a turbo-alternator group, 625 kva. 5000 volts. (Continuation of serial; former installments in no. 621, p. 166, no. 623, p. 212, and no. 627, p. 287.

Mining

Electricity in Mining, L. Fokes. Sci. & Art of Min., vol. 29, no. 2, Aug. 24, 1918, pp. 18-20, 5 figs. Safe operation of signaling apparatus; signaling circuits. (Continuation of serial.)

Motor Selection

Applying Engineering Principles Properly in Motor Selection, C. W. Squier. Elec. Ry. Jl., vol. 52, no. 12, Sept. 21, 1918, pp. 505-508, 14 figs. How to compare electric motors which appear to have the necessary characteristics for service designated and to select the one best adapted to meet given requirements.

Oil Fields

The Application of Electrical Power to Oilfield Requirements, J. Wilfred Burford. Jl. Instn. Petroleum Technologists, vol. 4, no. 16, June 1918, pp. 229-262, 4 figs., and (discussion) pp. 262-276. Economics gained by installation of electrical machinery; requirements of petroleum-producing industry; field this industry offers to manufacturers of electrical machines.

Printing

Electrically-Driven Printing Presses. Engineer, vol. 126, no. 3268, Aug. 16, 1918, 9 figs. Illustrations of arrangements and controllers; wiring diagrams.

Power Industry

Conditions in the Power Industry, L. W. Schmidt. Power, vol. 48, no. 14, Oct. 1, 1918, pp. 486-488. Digest of reports of United States consuls on power situation in various parts of world and influence of war upon this industry.

Water Works

Electric Drive for Water Works (Der elektrische Antrieb von Wasserversorgungsanlagen), Wintermeyer. Journal für Gasbeleuchtung, year 61, nos. 11 and 12, Mar. 16 and 23, pp. 126-128, 6 figs, and pp. 137-142, 10 figs. Discussion with diagrams of motor-generator connections.

Wind Power

The Use of Wind Power (Om udnyttlese af vindkraften), H. C. Vogt. Ingeniøren, vol. 27, no. 65, Aug. 14, 1918, pp. 451-452, 2 figs. (Continued from June 8.)

POWER PLANTS

Auxiliaries

Motor-Driven Auxiliaries, C. Grant. Mech. World, vol. 64, nos. 1648 and 1651, Aug. 2, and Aug. 23, 1918, pp. 52-53, and p. 88. Aug. 2: Rotary air pumps; circulating pumps. Aug. 23: Remarks on operation of feed pumps; chimney draft fans; generator cooling fans.

Cedar Rapids, Steam

Cedar Rapids Big Steam Plant. Power, vol. 48, no. 14, Oct. 1, 1918, pp. 478-485, 13 figs. Description of 16,000-kw. steam-turbine plant, with list of principal equipment.

Chimneys

Graphic Method of Chimney Design, H. M. Brayton. Power, vol. 48, no. 10, Sept. 3, 1918, pp. 349-350, 3 figs. Method of designing chimneys without calculations by use of charts and curves.

Rusting Steel Chimneys Coated with Concrete by Cement Gun. Eng. News-Rec., vol. 81, no. 13, Sept. 26, 1918, pp. 596-597, 3 figs. Reinforced-concrete shell is applied to outside of steel stacks.

Cincinnati, Steam

Cincinnati's New 100,000-Kilowatt Power Station. Elec. Rev., vol. 73, nos. 11 and 12, Sept. 14 and 21, 1918, pp. 397-400, 5 figs., and pp. 439-441, 5 figs. First installment describing station layout and mechanical equipment of Union Gas & Electric Company's new station with initial capacity of 50,000 kilowatts. Also published in Power, vol. 48, no. 10, Sept. 3, 1918, pp. 337-344, 14 figs.

Engine House

Rectangular Engine House Avoids Use of Turntable. Eng. News-Rec., vol. 81, no. 13, Sept. 26, 1918, pp. 593-594, 3 figs. Reinforced-concrete building has arched roof on timber lattice trusses; engine stalls have swinging doors.

Feedwater Heater

The Swartwout Feed-Water Heater and Receiver. Steam, vol. 22, no. 3, Sept. 1918, p. 80, 1 fig. Automatic apparatus designed to heat feedwater by use of exhaust steam.

Flexibility

Flexibility of Industrial Power Plants. Southern Engr., vol. 30, no. 2, Oct. 1918, p. 57, 1 fig. Typical connection diagram utilizing rotary converters for tying alternating and direct-current generators together.

Indicating Instruments

Management of the Power Plant, Robert June. Textile World Jl., vol. 54, no. 14, Oct. 5, 1918, pp. 77-81, 5 figs. Use and purpose of indicating instruments. Fourth of series.

Inspection

Need and Value of Boiler Inspection, A. L. G. Taylor. Power, vol. 48, no. 11, Sept. 10, 1918, pp. 389-390. Some instances of unsafe equipment revealed by inspection.

The Massachusetts Plan of Power-Plant Inspection and Coal Conservation, Thomas Hawley. Power, vol. 48, no. 9, Aug. 27, 1918, pp. 302-304. An exposition of plan to be followed in Massachusetts.

Mansfield, Coal and Natural Gas

More Energy for Mansfield District. Power Plant Eng., vol. 22, no. 18, Sept. 15, 1918, pp. 733-738, 12 figs. Description of new plant of Mansfield Electric Light & Power Co. at Melco, Ohio, using both natural gas and coal.

Montana, Hydroelectric

New Hydroelectric Plant of Montana Power Company, W. A. Scott. Elec. Rev., vol. 73, no. 13, Sept. 28, 1918, pp. 487-490, 2 figs. Details of recently completed Holter project.

Pennsylvania Salt Co., Steam

New Plant of the Pennsylvania Salt Manufacturing Company. Power, vol. 48, no. 12, Sept. 17, 1918, pp. 406-413, 10 figs. Description of a modern steam-turbine alternating-current plant with rotary-converter transformation to direct-current for electrolytic work.

Records

Power Plant Records of Operation, Ralph E. Turner. Power Plant Eng., vol. 22, no. 19, Oct. 1, 1918, pp. 799-803, 4 figs. Report sheets designed to aid engineer in obtaining and maintaining highest efficiency.

Rochester, Hydroelectric

Hydroelectric Development at Rochester. Power Plant Eng., vol. 22, no. 19, Oct. 1, 1918, pp. 779-782, 8 figs. Description of features of an hydroelectric plant.

Vibration

Prevention of Vibration in Power and Ventilation Plants, Charles L. Hubbard. Power Plant Eng., vol. 22, no. 19, Oct. 1, 1918, pp. 782-785, 11 figs. Causes of vibration and forms of foundations, supports, hangers and connections to prevent communication to building structure.

See also Chemical Technology (Water Softening); Hoisting and Conveying (Coal Handling).

PUMPS

Motor-Driven Pumps

Motor-Driven Pumps, Chas. Lawson. Southern Engr., vol. 30, no. 2, Oct. 1918, pp. 66-73, 6 figs. Pumping data; lift of pumps and pump control.

Triplex Pumps

Triplex Pumps, John H. Perry. Domestic Eng., vol. 84, no. 8, pp. 275-276, and 306, 4 figs. A few of the different kinds and how they work.

RAILROAD ENGINEERING, ELECTRIC

Circuit Breakers

High-Speed Circuit Breakers for Chicago, Milwaukee & St. Paul Electrification. C. H. Hill. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 623-626, 5 figs. Details of construction.

Cripples

The Disabled Soldier in Electric Railway Service. Electric Ry. Jl., vol. 52, no. 13, Sept. 28, 1918, pp. 579-582, 10 figs. Reclaiming the disabled soldier; blind men winding coils; one-armed men doing shop work.

Freight Transportation

The Problem of Freight Haulage, Harlow C. Clark. Aera, vol. 7, no. 2, Sept. 1918, pp. 103-106. Summary of electric railway freight situation in its connection with national transportation; causes preventing use of many miles of available track.

Locomotives

Advantages of Storage-Battery Locomotives, C. W. Chappelle. Coal Age, vol. 14, no. 10, Sept. 5, 1918, pp. 437-442, 3 figs. Paper read before Illinois Min. Inst., Peoria, Ill., May 1918, and discussion which followed.

Determination of the Proper Size of Storage-Battery Locomotive, Dever C. Ashmead. Coal Age, vol. 14, no. 12, Sept. 19, 1918, pp. 548-552, 2 figs. Explaining calculations of draw-bar pull and battery capacity.

Electric Shunting Locomotive, Lancashire & Yorkshire Ry. Ry. Gaz., vol. 29, no. 9, Aug. 30, 1918, p. 237, 1 fig. Particulars of an electric locomotive designed for shunting service at Clifton power station.

Rewinding and Testing Direct-Current Locomotive Armatures, Frank Huskinson. Coal Age, vol. 14, no. 12, Sept. 19, 1918, pp. 541-544, 16 figs. How mine-locomotive armatures may be rewound.

RAILROAD ENGINEERING, STEAM

Ballasting

A Typical Rock Ballasting Organization, F. H. C. Graves. Ry. Maintenance Engr., vol. 14, no. 9, Sept. 1918, pp. 310-311, 1 fig. Account of work done recently on a double-track eastern road with dense traffic.

Bolsters

Effect of Holes in the Sides of Box Bolsters, L. E. Endsley. Ry. Mech. Eng., vol. 92, no. 9, Sept. 1918, pp. 507-508, 3 figs. Results of a series of tests made on a box bolster with and without holes in the sides.

Brakes

Brake Performance with Heavy Trains. Ry. Gaz., vol. 29, no. 10, Sept. 6, 1918, p. 254. Remarks upon requirements of an efficient brake system based upon results obtained by the Virginian Ry. and described in same issue.

Car Cleaning

Passenger Car Cleaning on the Canadian Pacific Railway, E. Eley. Can. Ry. & Marine World, no. 248, Oct. 1918, p. 432. Description of process. Paper before Can. Ry Club, Montreal.

Car Lighting

Lighting of Railroad Cars by Coal Gas (Die Beleuchtung der Eisenbahnwagen mit Steinkohlengas), O. Hübner. Dingler's Polytechnisches Journal, vol. 333, no. 2, Jan. 26, 1918, pp. 10-12. From Journal für Gasbeleuchtung, year 59, pp. 417-425 and 435-439. Abstract of an extensive paper.

Cars, Passenger

New Cars for Special and Excursion Traffic. Ry. Gaz., vol. 29, no. 6, Aug. 9, 1918, pp. 159-160, 3 figs. General design of 26-ton, 82-passenger car prepared for Victorian Railways.

Cars, Standard

Railroad Administration's Standard Baggage Cars. Ry. Age, vol. 65, no. 13, Sept. 27, 1918, pp. 584-586, 3 figs. Details of designs for 60-ft. and 70-ft. cars of all-steel construction.

Steel Baggage Car for the United States Railroad Administration. Ry. Rev., vol. 63, no. 10, Sept. 7, 1918, pp. 341-343, 4 figs. General description of design adopted for all-steel 70-ft. baggage cars.

Cars, Wooden

Large Capacity Wooden Hopper Car. Ry. Mech. Eng., vol. 92, no. 9, Sept. 1918, pp. 509-512, 3 figs. Drawings and general data with description of wooden hopper car built by the N. & W.

Cranes

Gasoline Traveling Crane for Railroad Ash Pits. Ry. & Locomotive Eng., vol. 31, no. 10, Oct. 1918, pp. 305-307, 4 figs. General features of machines used by New York Central.

Draft Gear

Proper Draft Gear Maintenance, L. T. Canfield. Ry. Rev., vol. 63, no. 13, Sept. 28, 1918, pp. 460-462, 2 figs. Report of five tests of gears; recommendations as to inspection and repair. Paper read before Car Foreman's Assn. of Chicago, Sept. 1918.

Firing

Mechanical Stoking of Locomotives as Related to Smoke, W. S. Bartholomew. Ry. Rev., vol. 63, no. 10, Sept. 7, 1918, pp. 339-341. Résumé of stoker firing practice citing general points of advantage over hand firing, as well as specific instances in support of these claims. Read before Smoke Prevention Assn. at Newark, N. J., Aug. 22.

Freight Handling

The Mechanical Handling of Goods on Railways. Ry. Gaz., vol. 29, no. 10, Sept. 6, 1918, pp. 258-261, 14 figs. Handicaps imposed by wartime conditions on handling railway goods to rail truck from trader or Government consignee and vice versa.

Locomotives

Locomotive Stokers and Smoke Prevention, W. S. Bartholomew. Ry. Age, vol. 65, no. 10, Sept. 6, 1918, pp. 451-453. Résumé of stoker firing practice citing general points of advantage over hand firing, as well as specific instances in support of these claims. Read before Smoke Prevention Assn., Newark, N. J., Aug. 22.

Locomotive Terminal Detention Records. Ry. Gaz., vol. 29, no. 9, Aug. 30, 1918, pp. 241-242. Forms used by the Pennsylvania for gathering information regarding locomotive delays at terminals.

Making Good Engines Better on the Delaware, Lackawanna and Western. Ry. & Locomotive Eng., vol. 31, no. 10, Oct. 1918, p. 319, 3 figs. Results obtained from engines fitted with "Universal" steam chests and valves.

Renewable Stayheads for Locomotive Fireboxes. Engineer, vol. 126, no. 3270, Aug. 30, 1918, pp. 176-177, 5 figs. Description of a new renewable staybolt head and report of experiments and tests made upon it.

Results of Road Tests of N. & W. Mallet Locomotive, H. W. Reynolds. Ry. Mech. Eng., vol. 92, no. 9, Sept. 1918, pp. 502-503, 3 figs. General data on boiler, engine and locomotive performance, and results of tests.

Superheater Locomotive Performance. Ry. Age, vol. 65, no. 11, Sept. 13, 1918, pp. 498-499, 1 fig. Importance of maintenance; clean flues; dampers; effects of high water; lubrication and drifting.

Ten-Wheel and Mikado Type Locomotives for the Paris-Orleans Ry., F. C. Coleman. Ry. Rev., vol. 63, no. 8, Aug. 24, 1918, pp. 267-268, 2 figs. Description of two designs of locomotives recently introduced into heavy freight and passenger service in France.

Terminal Handling of Locomotives, H. C. Pickard. Can. Ry. & Marine World, no. 248, Oct. 1918, pp. 421-424, 11 figs. Suggestions regarding conservation of man power in cleaning fires in locomotives.

The Design and Uses of Tank Locomotives. Ry. Gaz., vol. 29, no. 6, Aug. 9, 1918, pp. 161-164, 6 figs. Claimed advantages of tank locomotives. Diagram drawings of the 0-6-4, 2-6-4, 4-6-2, 4-4-4 and 4-6-4 types.

Locomotives, Standard

Heavy Mikado Type Locomotive, United States Railroad Administration. Ry. Rev., vol. 63, no. 10, Sept. 7, 1918, pp. 331-334, 5 figs. Descriptive reference to first of heavy Mikado type locomotives to be constructed for U. S. R. R. Administration. Comparison with leading details of light Mikado type.

Heavy Standard Mikado Locomotive. Ry. Mech. Eng., vol. 92, no. 9, Sept. 1918, pp. 491-494, 7 figs. General description and principal data, with drawings.

Tonnage Rating of the Standard Locomotives, H. S. Vincent. Ry. Age, vol. 65, no. 14, Oct. 4, 1918, pp. 627-631, 3 charts. Charts of tonnage rating for U. S. Standard light Mikado, heavy Mikado and 8-wheel switching locomotives, with tables of frictional resistances of freight and passenger cars.

The U. S. Standard Heavy Mikado Type Locomotive. Ry. Age, vol. 65, no. 9, Aug. 30, 1918, pp. 375-376, 4 figs. General description, with drawings and principal data.

Rails

On the Stiffness and Relative Strength of Rails, E. W. Stoney. Indian Eng., vol. 63, no. 22, June 1, 1918, p. 304, 6 figs. Diagrams showing plots of results of experiments on deflection of rails in various positions by central dead loads.

Transverse Rail Fissues and the Derailment at Juniper, Ga. Ry. Rev., vol. 63, no. 9, Aug. 31, 1918, pp. 305-309, 9 figs. From report of engineer-physicist of Bureau of Safety, Interstate Commerce Commission, on failure by breaking in several places of a 12-year old 80-lb. A. S. C. E. section rail.

Salvage

Reclamation on the Southern Pacific, Frank A. Stanley. Ry. Mech. Eng., vol. 92, no. 9, Sept. 1918, pp. 505-506, 5 figs. Second installment. Description of extensive salvage work.

Shocks in Trains

Shocks in Long Passenger Trains, Robert Burgess. Southern & Southwestern Ry. Club, vol. 14, no. 10, July 1918, pp. 4-20 and (discussion) pp. 20-31. Causes producing them; suggestions to engine men.

Signals

Train Operation by Signal Indication on the Erie Railroad, Henry M. Sperry. Ry. Gaz., vol. 29, no. 9, Aug. 30, 1918, pp. 227-231, 4 figs. Summary of disadvantages experienced under manual block and improvement in train operation under automatic block. From the Railway Age.

Sleepers

The Green-Moore Patent Resilient Reinforced Concrete Sleepers. Ry. Gaz., vol. 29, no. 10, Sept 6, 1918, pp. 262-264, 10 figs. Figures and illustrations. Other concrete sleepers have been described in issues of May 13 and July 19, 1918.

Snow

Maintaining a Railroad Above the Clouds. Ry. Maintenance Engrs., vol. 14, no. 9, Sept. 1918, pp. 291-295, 9 figs. Problems encountered in handling snow and ice to keep open the Moffatt line reaching an elevation of over 11,000 ft.

The Southern Pacific's Snow Shed Problem, Geo. W. Rear. Ry. Gaz., vol. 29, no. 6, Aug. 9, 1918, pp. 158-159. Brief history of development of 29 miles of snow sheds and of problems involved in their maintenance. From Proc. Am. Ry. Bridge & Building Assn., 1917.

Superheaters

Superheater Unit Maintenance. Ry. Rev., vol. 63, no. 13, Sept. 28, 1918, pp. 479-482, 9 figs. Instructions for installation and care of superheater units. From Bulletin No. 4, by Locomotive Superheater Co., New York.

Terminals

Unit Operation of Railroad Terminals. Ry. Rev., vol. 63, no. 13, Sept. 28, 1918, pp. 455-458. From Preliminary Report of Committee on Yards and Terminals, Am. Railway Eng. Assn., issued in Bulletin 208.

Yards, Gravitation

Colwick Gravitation Yards, Great Northern Ry. Ry. Gaz., vol. 29, no. 7, Aug. 16, 1918, pp. 185-188, 5 figs. Plan and views of yard instituted for concentrating and remarshalling coal traffic to and from Notts and Derby mines.

See also *Factory Management (Stores)*; *Safety Engineering (Railroad Administration Safety Work)*; *Testing and Measurements (Track Scales)*.

REFRACTORIES

Brick, Inspection

Inspecting Refractory Brick, C. E. Nesbitt and M. L. Bell. Iron Age, vol. 102, no. 11, Sept 12, 1918, p. 630. Standard specification a necessity; results of some tests. From a paper before Am. Soc. for Testing Materials, June 1918.

Brick, Silica

The Manufacture of Silica Brick, H. Le Chatelier and B. Bogitch. Bul. Am. Inst. Min. Engrs., no. 141, Sept 1918, pp 1435-1462, 14 figs. Experiments on samples of a few grams conducted at the Sorbonne, Paris, for the purpose of determining necessary conditions in manufacture of high-grade brick.

High-Temperature Research

High Temperature Processes and Products (III), Chas. A. Darling. Jl. Royal Society of Arts, vol. 66, no. 3433, Sept. 6, 1918, pp. 649-656, 2 figs. Alundum and aloxite; artificial graphite; British processes; high-temperature research.

Structure

The Importance of Structure in Refractories, J. H. Kirkpatrick. Clay Worker, vol. 70, no. 2, Aug. 1918, pp. 137-139, 6 figs. Effect of structure on the ultimate quality of manufactured product. From the Effect of Size of Grog in Fire Clay Bodies, tech paper 104, Bureau of Standards.

Volatilization

Relative Volatilities of Refractory Materials, Wm. Roy Mott. Gen. Meeting Am. Electrochem. Soc., Oct. 2, 1918, Advanced Copy, Paper 1, pp. 1-34, 6 figs. Experimental study of order in which substances volatize in electric arc, distances at which their vapors condense from arc, and time to volatilize equal atomic quantities of elements or molecular quantities of compounds; theoretical considerations concerning ratios of absolute boiling points to melting points, and upon a universal vapor pressure curve applicable to all substances.

REFRIGERATION

Ice Making

Modern Raw Water Ice Making Plant. Ice & Refrigeration, vol. 55, no. 1, July 1, 1918, pp. 1-6, 9 figs. Details of motor-driven 100 ton plant with complete equipment.

Multiple-Effect Compression

Multiple-Effect Compression Ice Making and Refrigerating Machines. Engineering, vol. 106, no. 2747, Aug. 23, 1918, pp. 201, 7 figs. Diagram showing working cycle, indicator cards, and general description of a CO_2 multiple-effect compression refrigerating machine built by Seagers, Ltd., Dartford, Kent.

Storage-Room Refrigeration

Efficiency in Engineering, Eric H. Peterson. Ice & Refrigeration, vol. 55, no. 1, July 1, 1918, pp. 9-11, 5 figs. Charts showing refrigeration required for various temperatures in well-ventilated rooms and amount of pipe required for storage rooms.

ROADS AND PAVEMENTS

Concrete Roads

A Road Finisher That Produces Denser Concrete. Eng. & Cement World, vol. 13, no. 4, Aug. 15, 1918, p. 33, 1 fig. Device designed in 1913 by E. G. Carr, said to eliminate voids in concrete, and to have been used in construction of 400 miles of California's highways.

Pavement Planer Method of Finishing Concrete Roads, E. Earl Glass. Eng. & Contracting, vol. 50, no. 14, Oct. 2, 1918, pp. 318-319, 4 figs. Description of tools and methods used in making a concrete road in California.

Corners

Width of Roadway and Corner Cut Off, R. H. Whitten. Mun. Jl., vol. 45, no. 9, Aug. 31, 1918, pp. 166-167, 3 figs. Plans made by City Plan Commission of Cleveland for increasing corner radii and angle of vision.

Earth Roads

Method of Handling Materials for Concrete Roads. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, p. 31, 2 figs. Advantages of eliminating stock piles along route.

The Location, Construction and Maintenance of Earth Roads, H. R. MacKenzie. Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 181-186. Emphasizes engineering supervision of construction and constant attention to maintenance as principal factors necessary to make of an earth road a satisfactory highway.

Furnace-Slag Sub-Crust

Roads During and After the War, E. Purnell Hooley. Surveyor, vol. 54, no. 1385, Aug. 2, 1918, pp. 59-60. Use of furnace slag as sub-crust in macadam and telford roads. Paper before Instn. Mun. and County Engrs.

Highways

State-Aid Highway Work in Illinois, C. M. Hathaway. Am. City, vol. 19, no. 3, Sept. 1918, pp. 176-182, 3 figs. Widths, drainage, alignment and design of state-aid roads; discussion of construction materials: concrete, brick, bituminous, macadam and oiled earth; state-aid bridge work; grade-crossing problems. (Concluded.)

The Planning of a System of Rural Highways Under Conditions Existing in Province of Saskatchewan, W. M. Stewart. Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 189-192 and (discussion) 192-193. Classification of roads and determination of satisfactory type of surface to be used on a certain road from an estimate of volume and class of traffic to be provided for. Also published in Can. Engr., vol. 35, no. 10, Sept. 5, 1918, pp. 217-218.

Typical Specifications for Non-Bituminous Road Materials, Prevost Hubbard and Frank H. Jackson. U. S. Department of Agriculture, Bul. no. 704, professional paper, Aug. 30, 1918, 38 pp., 3 figs. For 19 common materials used in the construction and maintenance of various types of highways; descriptions of methods of testing to which reference is made in specifications.

Wood-Block Pavements

Proper Method of Application of Bituminous Filler for Creosoted Wood Block Pavements and Floors, Lambert T. Ericson. Eng. & Contracting, vol. 50, no. 14, Oct. 2, 1918, pp. 320-321, 2 figs. To prevent an excess of tar on pavement in hot weather, joints should be filled with tar or other substance at very high temperature so that joint will be well penetrated; details of proper application given.

SAFETY ENGINEERING

Acetylene, Dissolved, Cylinders for

Report of the Departmental Committee on Cylinders for Dissolved Acetylene (VI). Acetylene & Welding Jl., vol. 15, no. 179, Aug. 1918, pp. 146-150, 2 figs. Report on two samples of charcoal and on alternating pressure tests made on two dissolved acetylene cylinders. (Concluded.)

Blow-Off Tanks

Explosion of a Blow-off Tank. Travelers Standard, vol. 6, no. 9, Sept. 1918, pp. 177-181, 3 figs. Suggestions on construction and installation of blow-off tanks derived from an account of a recent explosion at a Cleveland manufacturing plant.

Construction Work

Benefit of Accident Prevention in Contracting, F. S. Robinson. Eng. & Contracting, vol. 50, no. 13, Sept. 25, 1918, pp. 311-312. Abstract of paper before Construction Section of National Safety Council, Sept. 1918.

Safety Engineering and Accident Prevention in Construction Work, Leo D. Woedtke. Eng. & Contracting, vol. 50, no. 13, Sept. 25, 1918, pp. 299-303. Accident prevention methods of Fred T. Ley & Co., Inc. Abstract from address before Construction Section Meeting of National Safety Council, Sept. 1918.

Dust Inhalation

Effects of Mine-Dust Inhalation, J. S. Haldane. Eng. & Min. Jl., vol. 106, no. 11, Sept. 14, 1918, pp. 475-477. Effects of various kinds of dusts when breathed by mine or mill workers. From paper submitted to Chem. Metallurgical & Min. Soc. of South Africa, and Instn. of Min. Engrs., London. Published also in Trans. Instn. Min. Engrs., vol. 55, part 4, Aug.-Sept. 1918, pp. 264-273 and (discussion) pp. 273-293.

A Short List of References on the Dust Hazard in Industry. Library of the National Workmen's Compensation Service Bureau, Reference List No. 3. A short bibliography.

Dust Explosions

Considerations Respecting Causes of Dust Explosions (Einiges über Staubexplosionem), G. Bauer. Zeitschrift für angewandte Chemie, year 30, no. 79, Oct. 2, 1917, pp. 239-240, 4 figs.

Explosives

Safety in the Use of Explosives, Arthur La Motte. Coal Age, vol. 14, no. 11, Sept. 12, 1918, pp. 490-496. Paper before Nat. Safety Council.

Fire Hazards

The Factory Fire Brigade (I), Paul Mason. Am. Indus., vol. 19, no. 2, Sept. 1918, pp. 14-16. Organization, equipment and discipline.

First Aid

Elementary First Aid for the Miner, W. A. Lynott and D. Harrington. Sci. & Art of Min., vol. 29, no. 2, Aug. 24, 1918, pp. 22-23. What to do at once when a fellow miner is hurt; general directions for caring for bleeding; miscellaneous precautions; dressing for broken bones; electric shock. From Miner's Circular 23, U. S. Bureau of Mines.

Flying Objects

Injury from Flying Objects, Chesla C. Sherlock. Am. Mach., vol. 49, no. 14, Oct. 3, 1918, pp. 625-627. Legal aspects of injuries received from flying objects discussed.

Headlights, Automobile

Automobile Headlights and Glare Reducing Devices, L. C. Porter. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 627-632, 13 figs. General discussion showing set of curves indicating candlepower necessary to "pick up" a man at various distances.

Dazzling Head Lamps. Autocar, vol. 41, no. 1192, Aug. 24, 1918, p. 188. Tests and standard specifications adopted in New York State.

Lightning Arresters

The Oxide Film Lightning Arrester, Crosby Field. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 597-601, 6 figs. Principle, construction and operation of instrument which consists essentially of an insulating film placed between a conductor and lead peroxide.

Machinery Movements

Abnormal Movement of Machinery, Chesla C. Sherlock. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 578-580. Discussion of accidents due to a sudden and abnormal movement of machinery, taking operator by surprise, and legal aspects.

Mine Accidents

Who Gets Hurt and Why. Coal Age, vol. 14, no. 11, Sept. 12, 1918, pp. 480-482, 7 figs. Details relating to total distribution of mine accidents, from records of Ellsworth Collieries.

Quarrying

Safe Practices in the Quarry and Mill, William H. Baker. Eng. & Cement World, vol. 13, no. 4, Aug. 15, 1918, pp. 53-54. Precautions taken at Hannibal, Mo., mills of Atlas Portland Cement Co. Abstract of paper before Nat. Safety Council.

Railroad Administration, Safety Work

Safety Program of Railroad Administration, Hiram W. Belnap. Ry. Rev., vol. 63, no. 12, Sept. 21, 1918, pp. 426-428. What it expects of different organizations in promotion of safety work. Abstract from paper before Nat. Safety Council, St. Louis.

Scaffolds

Safe Construction of Scaffolds and Falsework, T. F. Foltz. Eng. & Contracting, vol. 50, no. 12, Sept. 18, 1918, pp. 285-288. Abstract of paper before National Safety Council.

Small Shops

How Accident Prevention Work May Be Carried On in Small Companies, Wills Machlachlan. Am. Gas Eng. Jl., vol. 109, no. 14, Oct. 5, 1918, pp. 319-322. Suggestions in regard to equipment and organization. Paper before National Safety Congress.

Winding Engines

Safety in Winding Operations, J. A. Vaughan. South African Mining Jl., vol. 27, part 2, no. 1399, July 20, 1918, pp. 269-270. Remarks on safe handling of winding engine based on author's experience and compiled statistics of winding accidents in the Witwatersrand. Paper before the S. A. A. A. S.

See also Electrical Engineering (Excessive Voltages), (Safety Measures); Hoisting and Conveying (Safety Appliances), (Wire Ropes); Military Engineering (Mine Safety Appliances); Roads and Pavements (Corners).

SANITARY ENGINEERING

Plumbing

The Why and Wherefore of Sanitary Engineering, Arthur Bateman. Domestic Eng., vol. 84, no. 9, Aug. 31, 1918, pp. 315-317 and 344, 7 figs. Technical and scientific plumbing and sanitation. (Continuation of serial, preceding installment appeared July 13.)

Sewage Disposal

Sewage Disposal, Edward Willcox. Surveyor, vol. 54, no. 1385, Aug. 2, 1918, pp. 55-56. Camp sewage disposal; fertilizers from sewage; design of plants; Wolverhampton experiments; American research work. Assn. Mgrs. Sewage Disposal. (To be concluded.) Published also in Can. Engr., vol. 35, no. 10, Sept. 5, 1918, pp. 224-225.

Water Supply

Experience with Artesian Water Supply in Savannah, E. R. Conant. Am. City, vol. 19, no. 3, Sept. 1918, pp. 182-192, 1 fig. From paper before Am. Water Works Assn.

STANDARDS AND STANDARDIZATION

Gas-Meter Threads

Standardization of Gas Meter Threads and Connections in Germany (Die Vereinheitlichung der Gasmesser-Verschraubungen und

Verbindungen), D. Eisele. Journal für Gasbeleuchtung, year 61, no. 16, Apr. 20, 1918, pp. 181-183, 2 figs.

Pyrometers

Pyrometer Standardization. Ezer Griffiths and F. H. Schofield. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 222-237, 6 figs. Indicates temperature-scale basis of practical types and errors to which pyrometric observations are liable.

Screw Thread

The Relation of Screw-Thread Angles to Other Functions, H. J. Bingham Powell. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 571-573, 1 fig. Author sets forth his reasons for advocating adoption as an international standard the Whitworth thread.

Tubes, Seamless

International Aircraft Standards. Flight, vol. 10, no. 33, Aug. 15, 1918, p. 919. Specifications for alloy-steel seamless tubes of 200,000 lb. per sq. in. tensile strength. (Continued.)

See also Cement and Concrete (Portland Cement); Engineering Materials (Asphalt); Marine Engineering (Fabricated Ships), (Standard Vessels); Railroad Engineering, Steam (Locomotives, Standard).

STEAM ENGINEERING

Boiler Gage Glass

The Boiler Gage Glass. Wm. L. De Baufre. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 547-556, 2 figs. Explains how to determine actual weight of water contained in boiler, and gives corrections to be applied in tests where the gage-glass reading, the steam pressure and the rate of steaming at the end of a run are different from those obtaining at the beginning.

Boilers

Examination of Steam Boilers at Collieries. Edward Ingham. Colliery Guardian, vol. 116, no. 3007, Aug. 16, 1918, pp. 336-337, 9 figs. Typical defects found in inspection of boilers explained.

Steam-Boiler Regulation and Control. Albert A. Straub. Power, vol. 48, no. 13, Sept. 24, 1918, pp. 442-446, 6 figs. Brings out point that proper handling of damper for controlling draft for steam-boiler furnaces is of importance, and presents charts showing variation of temperature of escaping gases and of steam pressure.

Pressure Losses

Pressure Losses in Steam Plants. R. S. Hawley. Power Plant Eng., vol. 22, no. 18, Sept. 15, 1918, pp. 739-741, 2 figs. Causes: distinction between losses due to throttling and radiation.

Scale, Boiler-Tube

Boiler-Tube Scale; Its Removal with Kerosene as Practised at the Fuel-Oil Testing Plant, Albert M. Penn. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 512-517, 2 figs. 15 gal. of kerosene were poured into each lower drum with tin funnel, 100-lb. steam allowed to flow in and condense until water glass was three-quarters full. Photographs showing results and precautions advised.

Soot Removal

Soot Removal from Fire-Tube Boilers. Power, vol. 48, no. 9, Aug. 27, 1918, pp. 305-308, 13 figs. Rear-end and front-end blowers for return tubular boilers, rocking elements for internally fired boilers and gear-turned blowers for vertical boilers.

Steam, High-Pressure

Advantages of High Pressure and Superheat as Affecting Steam Plant Efficiency. Eskil Berg. Elec. Rev., vol. 73, no. 12, Sept. 21, 1918, pp. 444-447, 3 figs. Possibilities of higher steam pressures and temperatures for reducing mechanical and thermal losses in turbines.

The Uses of High-Pressure and High-Temperature Steam in Large Power Stations, J. H. Shaw. Contract Rec., vol. 32, no. 35, Aug. 28, 1918, pp. 703-705. Comparison of costs illustrated by schedule showing coal, steam and heat consumption for a 20,000-kw. machine running at 200 lb. and 350 lb. gage pressure at varying superheats and also at 500 lb. pressure absolute and 268 deg. fahr. superheat. Paper before Instn. Civ. Engrs. Also published in Elec. News, vol. 27, no. 17, Sept. 1, 1918, pp. 29-31, and in Elecn., vol. 81, no. 2100, Aug. 16, 1918, pp. 330-332, 5 figs.

Superheaters

General Construction and Maintenance of Superheater Units. Ry. & Locomotive Eng., vol. 31, no. 10, Oct. 1918, pp. 315-316, 4 figs. Device especially designed to prevent leakage in the joints and rapid deterioration of the ends of superheater pipes.

The Value of Superheated Steam at the Colliery and at Iron Works. Iron & Coal Trades Rev., vol. 97, no. 2635, Aug. 30, 1918, pp. 238-239, 2 figs. Description of Sugden superheater, with Stirling boiler and independently fired.

Turbines

A 35,000-kw. Turbine is Wrecked in Northwest Station, Chicago. Power, vol. 48, no. 10, Sept. 3, 1918, pp. 345-348, 4 figs. Detailed description of accident to 35,000-kw. turbine at Northwest Station, Chicago. Failure of nineteenth wheel probable cause of wreck.

Additional Power at Small Cost by Exhaust Steam Turbine. Can. Machy., vol. 20, no. 11, Sept. 12, 1918, pp. 317-318, 3 figs. Saving of fuel and boiler capacity obtained in paper mill by connecting steam turbines to line shaft through reduction gear.

The Forty-five Thousand Kilowatt Compound Turbine at Providence, R. I., J. P. Rigsby. Power, vol. 48, no. 9, Aug. 27, 1918, pp. 292-298, 9 figs. Illustrated description of 45,000-kw. cross compound reaction Westinghouse turbine at Providence, R. I.

Valves, Safety

Graphic Methods of Determining Size of Safety Valve, H. F. Gauss. Power, vol. 48, no. 12, Sept. 17, 1918, pp. 414-417, 4 figs. Reasons for increasing maximum allowable lifts above those permitted in the A.S.M.E. Code. Napier's formula for the flow of steam through an orifice used as a basis for constructing capacity curves. General solution by means of logarithmic charts.

Safety and Relief Valves, M. W. Rink. Jl. Am. Soc. Naval Engrs., vol. 30, no. 3, Aug. 1918, pp. 504-511, 7 figs. Construction and use of shifting and cylinder relief valves for a mixture of steam and water. From Marine Eng.

See also Engineering Materials (Boiler Plates); Power Generation and Selection (Exhaust Steam).

STEEL AND IRON

By-Products

By-Product Recovery in Iron and Steel Works. Engineering, vol. 106, no. 2747, pp. 206-207. Utilization of gas and other by-products of iron and steel works. From paper by A. Gouvy before Congrès du Génie Civil, Paris, March 1918.

Blast Furnaces

Fuel Economy in Blast Furnaces. T. C. Hutchinson. Iron Age, vol. 102, no. 12, Sept. 19, 1918, pp. 689-691, 3 figs. Cleaning the ore and size of bell factors in larger output and lower coke consumption in British practice; long life of furnace walls. From paper before Iron & Steel Inst., London, May 1918.

Casting

Sound Steel by Lateral Compression. Benjamin Talbot. Iron Age, vol. 102, no. 14, Oct. 3, 1918, pp. 836-838, 2 figs. British results from applying this principle to tap portion of slag; cheap refractory top of slag. From paper before Iron & Steel Inst., London, May 1918.

Corrosion

Corrosion of Iron and Steel, and its Prevention (VII). Abe Winters. Can. Machy., vol. 20, no. 9, Aug. 29, 1918, pp. 257-258. Considerations on sherardizing process (covering heated iron with zinc dust) with reference to temperature and time, and its commercial application.

Electric Steel

Electric Steel Making, Arthur V. Farr. Machy., vol. 25, no. 1, Sept. 1918, pp. 40-42, 9 figs. Importance and growth of electric-steel industry; cold-melt process and structure of electric steel.

The Electric Furnace in the Steel Casting Industry, W. E. Moore. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 331-332. Remarks on advantages and disadvantages of various processes of manufacturing steel—crucible melting, open-hearth, side-blow converter, and the electric furnace.

The New Electric Steel Plant at Toronto (La nouvelle aciérie électrique de Toronto). Génie Civil, vol. 72, no. 26, June 29, 1918, pp. 479-481, 3 figs. Plans, views and description.

Ferro-Alloys

The Manufacture of Ferro-Alloys in the Electric Furnace, R. M. Keeney. Min. Jl., vol. 122, no. 4334, Sept. 14, 1918, pp. 538-539. Ferrouranium. Paper before Am. Inst. Min. Engrs. (Continuation of serial.)

Iron, Molecular Instability

Molecular Instability Due to Magnetostriction (Instabilité moléculaire par le magnétostriction), D. Hurmuzescu. Revue Générale de l'Electricite, vol. 4, no. 7, Aug. 17, 1918, pp. 211-214, 1 fig. Results of experimental study which led author to assert that, unlike steel, iron under certain conditions possesses molecular instability.

Iron-Titanium Ores

On the Microstructure of Certain Titanium Iron Ores, Chas. H. Warren. Economic Geology, vol. 13, no. 6, Sept. 1918, pp. 419-446, 12 figs. Experimental study of titanium-iron-oxide minerals, including a number of ilmenites from different parts, carried out on large Leitz metallographic microscope, using a small 4 ampere arc as source of light.

Ore Resources

Notes on Certain Iron Ore Resources of the World, C. E. Harder, W. Lindgren, C. M. Weld, A. C. Spencer, H. P. Bain, and Sidney Paige. Bul. Am. Inst. Min. Engrs., no. 141, Sept. 1918, pp. 1471-1496. Brazil, Scandinavia, Cuba, Southern Europe, China, and Alsace-Lorraine.

Application of Optical Pyrometry in Steel Works Practice, J. N. Greenwood. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 295-308, 4 figs. Comparison of various conditions of use of an optical pyrometer in taking temperatures of liquid steel in the open with calibration conditions; errors due to emissivity; polarization of emitted light, and lack of monochromatism; technical defects of the Cambridge type; suggestion to obtain control of steel-making process pyrometrically.

Pyrometry

Notes on Pyrometry from the Standpoint of Ferrous Metallurgy, W. H. Hatfield. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 289-294. Account of methods to control temperature used in large armament works.

Temperature Determinations of Liquid Steel, A. McCance. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 309-310. Work done at the Parkhead Steel Works to develop a system of controlling the temperature in an open-hearth furnace by an optical pyrometer.

The Determination of the Temperature of Liquid Steel Under Industrial Conditions, Cosmo Johns. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 280-288. Account of author's experience; suggestion to adopt as standard an optical pyrometer using monochromatic light $\lambda = 0.65\ \mu$.

Semi-Steel

Steel Mixture Iron—The Use of Scrap Steel in Pig Iron Mixtures. Contract Rec., vol. 32, no. 37, Sept. 11, 1918, pp. 731-732. Factors involved in absorption of carbon from coke by steel during cupola melting and experiment illustrating this absorption; results obtained from melting steel borings and crop ends from smithy in a cupola together with 10 per cent ferrosilicon. From the Engineer, London.

Steel, Hardness and Tensile Strength

Tensile Strength and Hardness of Steel, H. M. Brayton. Iron Age, vol. 102, no. 11, Sept. 12, 1918, pp. 627-629, 3 figs. Their relation shown by means of graphical charts which give either variable in terms of the other.

Steel Mills

Fuel Economy in a Modern Steel Works, Benjamin Talbot. Colliery Guardian, vol. 116, no. 3010, Sept. 6, 1918, pp. 493-494. Examination of most economical fuel consumption possible to obtain in practice in a modern steel works. Appendix II to Carbonization Committee's Report, Board of Trade. Also published in Iron & Coal Trades Rev., vol. 97, no. 2634, Aug. 23, 1918, pp. 210.

Mechanical and Electrical Equipment of a Southern Steel Mill. Southern Engr., vol. 30, no. 2, Oct. 1918, pp. 36-43, 12 figs. Waste-heat boiler installation, mixed-pressure turbines, motor drive for billet mills, roughing mills and other machinery, motor control.

Tubes, Seamless

Tubes and Tubular Structures, W. W. Hackett and A. G. Hackett. Aviation, vol. 5, no. 4, Sept. 15, 1918, pp. 230-234. Review of method of manufacturing seamless steel tubing, of difficulties to be overcome, and forms of manipulation which it is possible to put upon good quality steel tubing; account of tests carried out on specimen tubes, under various conditions, and joined together in different ways. Paper before Aeronautical Soc. of Great Britain.

Wire-Rod Mills

Designing Passes for Wire Rod Mill Roll Train, W. S. Standiford. Am. Mach., vol. 49, no. 14, Oct. 14, 1918, pp. 601-604, 3 figs. Design of roll passes and difficulties encountered in manufacture of rods.

See also Engineering Materials (Semi-Steel); Foundry (Fluidity of Iron).

TESTING AND MEASUREMENTS

Calorimeters

Some Points Regarding Calorimeter Efficiency, Walter P. White. Jl. Franklin Inst., vol. 186, no. 3, Sept. 1918, pp. 279-287. Sources of calorimetric error and considerations on different types of these instruments with reference to moderately high precision demanded in commercial work.

Electrical Apparatus

The Engineering Evolution of Electrical Apparatus (XXXII), Chas R. Riker. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 357-362, 14 figs. Synchroscopes; power-factor meters; frequency meters; ground detectors; compensated instruments.

Engine Testing

The New Duesenberg Aero Engine Test House. Aerial Age, vol. 8, no. 2, Sept. 23, 1918, pp. 66-67, 4 figs. Processes followed at laboratories of Duesenberg Motors Corporation in analyses of construction materials.

Hardness Testing

Brinell Hardness Test, J. G. Ayers, Jr. Iron Age, vol. 102, no. 10, Sept. 5, 1918, pp. 581-582, 3 figs. New method insuring quick commercial results of sufficient accuracy. From paper before Am. Soc. for Testing Materials.

High-Temperature Measurements

The Automatic Control and Measurement of High Temperatures, Richard P. Brown. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 246-252. Operation of Brown heat meter.

Meters, Electric

Meter Installation for Determining Energy Accurately in Three-Phase Systems (Sur un montage des compteurs enregistrant l'énergie des postes triphasés permettant la détermination de l'énergie magnétisante et donnant une plus grande sécurité de bon fonctionnement), P. Bourguignon. Revue Générale de l'Electricité, vol. 4, no. 7, Aug. 17, 1918, pp. 214-217, 2 figs. Method to determine cos Φ by means of two monophase meters.

Pyrometry

Base-Metal Thermoelectric Pyrometers, Chas. R. Darling. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 344-347, 2 figs. Couples employed: iron-constantan, two iron-nickel alloys of different composition, and two different nickel-chrome alloys known as Hoskins' alloys.

Bibliography on Pyrometers, Robert Hadfield. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 362-372. Pamphlets, papers and cuttings; British and American patents; books.

Note on the Wiborgh Pyrometer, John G. A. Rhodin. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 260-261, 4 figs. Description of instrument. From Jernkontorets Annaler.

Notes on the Remediable Causes of Unreliability Encountered in Thermoelectric Pyrometry, Especially in Systems of the Base-Metal Type, C. E. M. Stone. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 348-355, 1 fig., and (discussion) pp. 355-359. Efforts of various manufacturers to construct an efficient pyrometer by using base-metal thermocouples in conjunction with pivot millivoltmeters.

Optical Pyrometry in Non-Ferrous Metallurgy, F. G. Donnan. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 276-279, 2 figs. Corrections necessary in reading of optical pyrometers when measuring temperatures of molten metal, in the cases of gold and copper.

Pyrometers, Their Construction and Repair, J. V. Lucas. Am. Mach., vol. 49, no. 11, Sept. 12, 1918, pp. 471-477, 17 figs. Description of construction and of minor repairs which can be made without returning instrument to maker.

The Measurement of High Temperatures by Means of Pottery Materials, Henry Watkin. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 330-340, 10 figs., and (discussion) pp. 341-343, 1 fig. Types of pyrometer based on principle of contraction of pottery materials under influence of heat.

The Relation of Optical and Radiation Pyrometry to Modern Physics, Paul D. Foote. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 238-245, 1 fig. Study of constants in Planck's spectral distribution law and Stefan-Boltzman law of radiation in their relation with constants of other important radiation laws.

Thermocouples

The Advantage of Burying the Cold-Junction of a Thermocouple as a Means of Maintaining it at a Constant Temperature, Robert S. Whipple. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 253-259, 5 figs. Method used in connection with experimental work at Cambridge Scientific Instrument Co.

Track Scales

War Time Standardization of Railroad Track Scales, C. A. Briggs. Scale Jl., vol. 4, no. 12, Sept. 10, 1918, pp. 9-10. Recountal of recent efforts of Bureau of Standards. Paper before Scale Mfrs.' Assn.

Working Stresses for Railroad Track Scale Design. Scale Jl., vol. 4, no. 12, Sept. 10, 1918, p. 7, 1 fig. Nat. Bureau of Standards data including allowances for import carried by moving loads.

Ultra-Violet Rays

Ultra-Violet Light, Its Application in Chemical Arts (XIV), Carleton Ellis and A. A. Wells. Chem. Engr., vol. 26, no. 7, June 1918, pp. 263-272. Testing smokeless powder and many organic compounds by effect produced on them with exposure to ultra-violet radiations.

See also Aeronautics (Materials of Construction); Electrical Engineering (Recording Instruments); Power Plants (Indicating Instruments); Steel and Iron (Pyrometry).

TRANSPORTATION

Delivery Zones

How Delivery Zones Will Reduce Freight Traffic, E. Amberg. Am. City, vol. 19, no. 3, Sept. 1918, pp. 179-180, 2 figs. Feature of plan being worked out by U. S. Railroad Administration to reduce congestion of freight traffic in New York.

Freight Handling

Reorganization of Loading and Unloading, C. H. Humphreys. Motor Traction, vol. 27, no. 705, Sept. 4, 1918, pp. 165-168, 2 figs. Suggests forms of standard chassis which can be fitted with two or three standard type bodies, and apparatus for loading and unloading certain classes of goods.

WOOD AND TIMBER

Decomposition

Durability of Untreated Piling Above Mean Low Tide, C. H. Teasdale and M. E. Thorne. Ry. Gaz., vol. 29, no. 10, Sept. 6, 1918, p. 257. Report on protection afforded to timber by saturation above water level. Prepared by questionnaire method at U. S. Forest Products Laboratory.

Fungi, the Cause of Decomposition of Timber, P. H. Dudley. Wood-Preserving, vol. 5, no. 3, July-Sept. 1918, pp. 26-35, 10 figs. Brief details of the life history of trees and fungi.

Pipes

The Possibilities of Creosoted Douglas Fir Wood Stave Pipe for Use in Irrigation and Water Supply Systems (II), O. P. M. Goss. Wood-Preserving, vol. 5, no. 3, July-Sept. 1918, pp. 37-38, 1 fig. Experimental work in perforating outer surface of staves with small holes systematically spaced.

Poles

Economics of Pole Timber, Ernest F. Hartman. Elec. World, vol. 72, no. 13, Sept. 28, 1918, pp. 590-591, 1 fig. Preservation of poles and arresting of decay in advanced stages.

Maintenance Cost of Poles, W. F. Goltra. Wood-Preserving, vol. 5, no. 3, July-Sept. 1918, pp. 35-36. Table showing discounted value of annual return of one pole, obtainable for 1 to 55 years.

Uses

The Uses of Wood. The Place of the Wooden Roof in Civilization (IV). Am. Forestry, vol. 24, nos. 296 and 297, Aug. 1918 and Sept. 1918, pp. 473-482, 15 figs., and pp. 533-541, 21 figs. Various phases of subject, from beginnings in the forests through processes of logging, lumbering, transportation and milling, considering details in field of utilization and manufacture of wood.

See also Fuels and Firing (Wood); Pipe (Wood); Roads and Pavements (Wood-Block Pavements).

WOODWORKING MACHINERY

Propeller-Shaping Machine

Aero-Propeller Shaping Machine. Can. Machy., vol. 20, no. 8, Aug. 22, 1918, pp. 227-228, 2 figs. Ransome-Kerr machine which works by copying the profile of a model blade.

VARIA

Abaci

The Construction of Abaci, A. B. Eason. Elecn., vol. 81, no. 2100, Aug. 16, 1918, pp. 339-341, 6 figs. How to draw up abaci for use in solving various common engineering problems without using tables and slide rules.

Automobile Insurance

List of References on Automobile Insurance in the Library of the National Workman's Compensation Service Bureau. Reference List No. 5. A short bibliography.

Diamonds

The Diamond, Charles Parsons. Sci. Am. Supp., vol. 86, no. 2225, Aug. 24, 1918, pp. 124-126, 12 figs. Theories and experiments in forming artificial gems. From lecture before Inst. of Metals, published in The Engineer (London).

Education

Broader Foundation Demanded for Engineering Education, Frederick Bass. Eng. News-Rec., vol. 81, no. 13, Sept. 26, 1918, pp. 582-583. Higher aims also needed; students' longings not met: vision of great practitioners should guide educators.

The Engineer and the War, M. E. Cooley. Jl. Engrs. Club of St. Louis, vol. 3, no. 4, July-Aug. 1918, pp. 211-213. Tabular presentation of output of all engineering schools of United States since 1895. From Michigan Tecanic.

Electrical Industry

Business Conditions in the Electrical Industry. Elec. Rev., vol. 73, no. 10, Sept. 7, 1918, pp. 363-384. A summary of views obtained from leading manufacturers and jobbers regarding present conditions in industry and outlook for the future.

Engineers, Legal Status

Legislation Concerning the Status of Engineers, F. H. Peters. Jl. Eng. Inst. of Can., vol. 1, no. 5, Sept. 1918, pp. 217-220 and (discussion) 220-221. Account of work done by Inst. toward establishing some legal standard and make it possible to control organization.

Foreign Markets

Testing the Buying Power of a Foreign Market, L. W. Schmidt. Am. Mach., vol. 49, no. 13, Sept. 26, 1918, pp. 581-584. Suggestions as to ways of estimating probable markets to see whether it will pay to send representatives; sources of information and how it can be judged and collated.

Latitude Determinations

Common Methods of Determining Latitude and Azimuth Useful to Engineers and Surveyors, Harry J. Wolf. Quarterly of the Colo. School of Mines, vol. 13, no. 3, July 1918, pp. 3-13. Latitude by observing altitude of sun at noon or that of polaris at culmination; azimuth by altitude of sun, or equal a. m. and p. m. altitudes of sun, by polaris at elongation culmination or any hour-angle.

Microtelescope

Optical Devices Aid Science and Industry. Can. Machy., vol. 20, no. 9, Sept. 5, 1918, p. 301, 5 figs. Recently produced microtelescope consisting of a microscope of ordinary construction carrying a short-focus telescope objective and tube below the stage.

BRITISH ENGINEERING STANDARDS ASSOCIATION

Papers on Standardization Work of This Important Association, with Special Reference to Screw Threads, Screw-Thread Gages and Tolerances

IN view of the standardization work in process by the Screw-Thread Commission of the United States Department of Commerce, the Machine-Shop Session of the Annual Meeting on Wednesday, December 4, will be devoted mainly to the production and testing of screw gages and standardization work in this connection. The work of the British Engineering Standards Association is reviewed in the following papers and a paper by Frank O. Wells, on the production of gages, is also given in this number. In the November issue appeared a paper by H. L. Van Keuren of the U. S. Bureau of Standards on methods of testing and standardizing gages.

SUMMARY OF THE WORK OF THE ASSOCIATION

By C. le Maistre,[1] London, England

THE insistent demand created by the war for the maximum output of manufactured material in the minimum of time has naturally brought to the fore those means by which economy in production can be effected, and in this way standardization is coming into its own. Indeed, standardization in the engineering world has become almost a word to conjure with, but like all good things, it must be taken in moderation, and the standards recommended must, by a process of periodic revision, be kept abreast of invention and progress; otherwise there is the danger of standardization becoming crystallization.

It may fairly be said that the primary objects of standardization are to secure interchangeability of parts, to cheapen manufacture by eliminating the waste of time and material entailed in producing a multiplicity of designs for one and the same purpose, and also to expedite delivery and so reduce maintenance charges and stores.

Seventeen years ago, however, neither the necessity nor the value of work of this character and still less its intimate relation to economy and speed of production was at all generally recognized, and it was to remedy the chaotic state of things then existing in the engineering industry of Great Britain that the late Sir John Wolfe Barry, K. C. B., F. R. S., in 1901 took the initial steps, when he brought the subject to the notice of the Council of the Institution of Civil Engineers, which resulted in the formation of the British Engineering Standards Committee.

From its inception certain definite principles have governed the work of the Committee, amongst which may be placed in the forefront the community of interest of producer and consumer, which is, in fact, the corner stone of the organization. It was also realized that the Committee should not be an academical body, but an industrial organization in the closest touch with practical requirements and modern scientific knowledge and discovery; that it should only undertake standardization to meet recognized wants, and then only at the request of the principal interests concerned; that it should confine itself to setting-up standards, leaving it to the user to satisfy himself by inspection and supervision that the standards were being adhered to; and, most important of all, that periodic revision of the standards should be undertaken so that improvements might be incorporated, the various industries thus being prevented from becoming stereotyped and their methods hidebound.

From the small nucleus of seven members who formed the original Committee, a far-reaching organization has developed with some 160 committees, sub-committees and panels, including in all over 900 members and dealing under one central authority with standards relating to practically the whole field of engineering. Thus for many years past, the British Engineering Standards Association, as it is now called, has provided the neutral ground upon which the producer and the consumer, including the technical officers of the large spending departments of the Government and the great classification societies, have met and considered this subject of such vital interest to the well-being of the engineering industry of the country.

To the observance of the democratic and progressive principles outlined, coupled with the devoted labor of its members freely giving their time and experience to the work, often at great personal expense and inconvenience, may be attributed the increasing success of this work of growing national importance.

A large number of British Standard Specifications and Reports have already been issued and these are constantly being added to, the most recent additions being the specifications for aircraft material and parts drawn up at the request of the Department of Aircraft Production of the Ministry of Munitions, for whom the Association acts practically as the Departmental Specifications Committee.

The standardization of steel sectional material was the first work taken up by the Committee. The British standards for this material, so important in the construction of ships, bridges and underframes for railway wagons, have had a very wide adoption. The total number of sections is some 175, and the recently formed Mercantile Section of the Admiralty, as a war measure, was able to select from this list a largely reduced number and so put into operation an exceedingly economical measure with but little delay. The testing requirements of Lloyd's Register and the other great classification societies and the Board of Trade have been unified through the work of the Committee.

It would appear from the steelmakers' returns for 1913 giving the tonnage of lengths rolled of each section that 95.7 per cent had been produced by standard rolls and only 4.3 per cent by non-standard rolls, the work thus having proved of immense utility to the steelmakers.

In the case of tramway rails, standardization has had the result of reducing to a minimum the sections required; at the present time there are only five standard sections as against over 70 sections prior to the advent of the committee. These sections are now being reduced to three, one being a special section for interurban tramways operating at a higher speed than those of the towns.

As a further instance of the benefit of the Committee's labors may be mentioned the standard specification for Portland cement, which is practically universally adopted throughout the country.

In regard to the electrical industry, the most important piece of work has been the issue of standardization rules for electrical machinery, in the drafting of which much benefit has accrued through the close and very cordial coöperation of the Standards Committee of the American Institute of Electrical Engineers.

A large amount of standardization has been effected also for the automobile industry, especially in regard to the special steels used.

From time to time Government Departments have called upon the Standards Committee to carry out work for them, as, for instance, in the case of the Ministry of Munitions in relation to the question of screw-thread tolerances and the gauging of screws generally. Then the Indian Government requested the Committee to undertake the question of standard designs for loco-

[1] Secretary, British Engineering Standards Association, 28 Victoria St., Westminster.

For presentation at the Annual Meeting, December 3 to 6, 1918, of The American Society of Mechanical Engineers. All papers are subject to revision.

motives, and these have proved of immense value. The Road Board also asked the Committee to draft specifications for road material. As already mentioned, at the request of the Department of Aircraft Production, the Association is dealing with the specifications for aircraft materials and parts as a war measure for the Department. To carry on this important work a large number of sub-committees have been formed, consisting of officers from the technical, supply and inspection departments, together with representatives from the various trade organizations concerned; the specifications in this case are not published by the Association in the ordinary way, but are issued to the Department of Aircraft Production, by whom they are sent to the various manufacturers of aircraft material on the Government list, in this way becoming obligatory.

In regard to the question of finance, the funds for carrying out the work of the Committee have been provided by the Government and the industries concerned. In 1903 the Government included in the estimates a substantial contribution, which was subsequently extended for the years 1904-5-6 by a grant-in-aid equal to the amount contributed by the supporting institutions, manufacturers and others. This was continued on a smaller scale down to 1916, and a further grant on the same condition is being continued to March, 1919. The Indian Government has been a generous supporter of the Committee and the Governments of other Overseas Dominions have also given financial assistance. A liberal response to the Committee's appeal for funds has been made by the engineering industry of the country and also by railway, shipping and other companies, and by some of the Local Government Boards and the tramway and electricity authorities.

The expenses of the whole organization up to the war were under £4000 a year, but, owing to the widening of the field of its labors, this amount has been very greatly exceeded.

The Committee, as many are aware, has recently become incorporated as an Association, under license of the Board of Trade, in order to enable it in the first place to continue the work carried out by the Engineering Standards Committee, viz. to coördinate the efforts of producers and users for the improvement and standardization of engineering materials, and, secondly, in order to secure undisputed legal right to its mark or brand to be attached by manufacturers to their products as a hall-mark of goods made in accordance with the British Standard Specifications.

The chairman of the Association is Sir Archibald Denny, Bart., who succeeded the late Sir John Wolfe Barry, to whose guiding hand during the many years of his chairmanship, so much of the success of the movement is due.

The Main Committee, as the governing Committee is called, consists of members nominated by the leading technical institutions, viz., the Institution of Civil Engineers, Mechanical Engineers, the Iron and Steel Institute, the Naval Architects, and the Institution of Electrical Engineers; there are also two representatives of the Federation of British Industries; and three members, not representative of any institution or association, but elected for their eminence in the profession.

The members of the Federation of British Industries give the various trade organizations connected with the work of standardization a direct channel through which to place their views before the Main or executive Committee of the Association.

Rotation of office is provided in that the chairman and vice-chairman and one-third of the group of members retire annually being eligible for reelection.

The Main Committee is the sole executive authority and all specifications and reports are presented to it for final adoption. The procedure before embarking on any new subject is to ascertain by means of a representative conference that there is a volume of opinion favorable to the work being undertaken. If such is the case, the Main Committee nominates the chairman of a sectional committee to take up the work in question, this committee being formed of technical officers representative of the various Government Departments interested, representatives of the trade organizations concerned, and lastly experts in the subject to be dealt with. The Main Committee does not dictate in any way either the number of members or the personnel of the sectional committee, only reserving to itself the right to nominate the chairman, though naturally it is guided in this matter also by the advice of the members.

Although the activities of the Association have in the main been confined to the home country, a considerable amount of work of an international character has been undertaken. At the present time the Association is coöperating with the American Institute of Electrical Engineers in several directions in regard to electrical apparatus generally. Then there is the great question of the standardization of screw threads and also of milling cutters and small tools, in connection with which The American Society of Mechanical Engineers will be able to render most valuable assistance. Indeed, there is a wide field for Anglo-American agreement on engineering standardization generally and the Association looks forward to a large measure of intimate coöperation with this object in view.

In connection also with its labors outside the home country, the Association is developing a scheme for assisting in procuring the wider dissemination of British Standards, and is undertaking the translation of its more important reports into various foreign languages, as well as setting up, with the assistance of the Overseas Department of the Board of Trade, Local Committees of British Engineers and Traders in some of the more important trading centres of the world.

That the value and utility of the work of the Association is becoming more and more recognized both at home and abroad is evidenced by the amount of new work it is continually being invited to undertake as well as by the inquiries received from all parts of the world both with reference to the standards and to the organization itself.

The most recent addition to the Association's activities is that of the standardization of the details in the construction of ships and their machinery. A conference recently convened at the instance of the Board of Trade, and representing Government Departments, shipowners, shipbuilders and engineers, classification societies and consulting and naval architects, has unanimously decided to recommend to the Main Committee the setting up of a complete section to deal with this branch of engineering, in which, in common with all others, economic production, fostered by interchangeability of detailed parts, is of such vital importance.

This brief account will, it is hoped, be sufficient to show that throughout the Empire, British Standards are receiving increased recognition as being of direct utility to the engineering industry generally. Standardization, after all, is no more and no less than proper coördination. To effect it may necessitate the sinking of much personal opinion, but, if its goal, through wideness of outlook and unity of thought and action, is the benefit of the community as a whole, standardization as a coördinated endeavor is bound increasingly to benefit humanity at large.

Technical Paper 178 of the U. S. Bureau of Mines, by S. M. Darling, which has been recently issued, deals with the characteristics and utilization of lignite. There are considerable lignite deposits in the Dakotas and Minnesota, yet the greater part of the fuel used in these states is imported from distant coal fields, involving long hauls. Mr. Darling's notes are intended to point out some of the ways in which that fuel may be used economically. It cannot be used in its raw form, except in the immediate neighborhood of the mine, because it contains 30 per cent of moisture. Instead, it must be modified so as to produce several products, each adapted to a particular commercial need, such as: Dried lignite for use with stokers or in gas producers; powdered fuel for use in furnaces, kilns and locomotives; dried briquets for large hand-fired industrial furnaces; carbonized lignite for use in suction producers; carbonized lignite briquets for use in domestic stoves and furnaces; and sulphate of ammonia and producer gas as obtained by the Mond process.

This publication gives much information as to the by-products obtainable from lignite and will be of value to those studying the problem of utilizing lignite as fuel.

THE WORK OF THE BRITISH ENGINEERING STANDARDS ASSOCIATION ON SCREW THREADS AND LIMIT GAGES

By SIR RICHARD GLAZEBROOK,[1] C.B., F.R.S., TEDDINGTON, ENGLAND

THE following notes give a résumé of the work done by the British Engineering Standards Association in connection with screw threads and limit gaging.

The importance of problems dealing with limits and gages was recognized at an early date by the Main Standards Committee, which appointed a Committee on Screw Threads and Limit Gages in February 1903. Two years later, after 23 meetings at which careful inquiries were made, and the merits of various threads, in particular of the Sellers Thread, were studied, the Committee finally decided that:

Having regard to the evidence laid before the Committee, and to the fact that the Whitworth thread is in general use throughout the country, the Committee do not recommend any departure from this form of thread.

It appeared, however, that there was a very general demand for a series of screws having finer pitches than those of the Whitworth form, and this led to the introduction of the British Standard Fine, B.S.F., series of pitches.

The Report contains tables giving the standard dimensions of these two series of screw threads, B.S.W. and B.S.F., and also of the British Association Series. It contains besides the following definitions:

Tolerance. A difference in dimensions prescribed in order to tolerate unavoidable imperfections of workmanship.

Allowance. A difference in dimensions, prescribed in order to allow of various qualities of fit.

Clearance. A difference in dimensions, or in the shape of the surface, prescribed in order that two surfaces, or parts of surfaces, may be clear of one another.

Effective Diameter of a Screw. The effective diameter of a screw having a single thread is the length of a line drawn through the axis and at right angles to it, measured between the points where the line cuts the slopes of the thread.

Core Diameter. The core diameter is twice the minimum radius of a screw, measured at right angles to the axis.

Full Diameter. The full diameter is twice the maximum radius of a screw, measured at right angles to the axis.

Crest. The crest is the prominent part of the thread, whether of the male screw or of the female screw.

Root. The root is the bottom of the groove of the thread, whether of the male screw or of the female screw.

Slope of Thread. The slope of thread is the straight part of the thread which connects the crests and roots.

Angle of Thread. The angle of thread is the angle between the slopes, measured in the axial plane.

Pitch. The pitch is the distance in inches measured along a line parallel to the axis of the screw between the point where it cuts any thread of the screw and the point at which it next meets the corresponding part of the same thread. *The reciprocal of the pitch* measures the number of turns per inch or millimetre as the case may be.

Initial Report on Screw-Thread Tolerances

The Committee next turned its attention to limits for plain cylindrical work and to limit gages for screw threads. The preparation of reports on these subjects involved a long series of experiments and measurements, many of which were carried out at the National Physical Laboratory.

The object of specifying tolerances was to secure interchangeability, and a little consideration showed the Committee that the element whose error most seriously affects interchangeability is the pitch; attention was drawn to the fact that the consequences of an error in pitch manifest themselves not only in the direction of the axis, but also at right angles to it, and it was shown that with an angular thread of angle α, a bolt and a nut of t inches in thickness, having a relative difference of pitch of p mils per inch, must have a difference of effective diameter of $pt \cot \alpha/2$ mils, in order that they may go together; pt clearly measures the total pitch difference of the screw and nut in the length engaged, so that the importance of the pitch error per length of engagement was appreciated from the commencement of the work. In the case of the Whitworth thread, $\alpha = 55$ deg., and $\cot \alpha/2$ is approximately 2, so that the rule was formed that for a screw of faulty pitch to pair with a perfect nut, the effective diameter must be reduced by twice the pitch error per length of engagement.

In the words of the report, the Committee had before them two separate matters to decide:

a To lay down tolerances on full core and effective diameters to cover the wear of tools and unavoidable imperfections of measurement, and to prescribe minimum allowances in order that bolts and nuts may be assembled freely.

b To decide what errors in pitch could be permitted in ordinary practice, having regard to the allowances in effective diameter which they entail.

The report contains the answers to these questions. Formulæ are given for the various tolerances and allowances, and a table of values worked out for the two series of threads.

Table 1 gives the tolerances for bolts $\frac{1}{4}$ in., $\frac{1}{2}$ in., 1 in., 2 in. and 3 in. in diameter for B.S.W. threads.

Further Investigations of Tolerances

No further investigations were undertaken until the comparatively recent reorganization of a Sectional Committee on Machine Parts, their Gaging and Nomenclature and a Sub-Committee on Screw Threads for all purposes and their gaging.

War conditions have increased enormously the demand for interchangeable screws, while the experience gained has enabled a clearer idea to be formed of the real essentials of interchangeability and of the difficulty of securing them. It has become increasingly clear that fit at crest and root is in most cases unimportant. Large tolerances can be given on these dimensions: some authorities think it desirable to prescribe actual clearances, i.e., to formulate such dimensions that the bolt and nut can never come into contact at these points. In any case, it is agreed that for the work, an adherence to the exact amount of rounding at crest and root specified in the Whitworth thread is not needed. The elements which do matter are the pitch and the effective diameter: i.e., the lead and pitch diameter, to use the American terms, and also, to a less degree, the angle. The conditions applicable to munitions, guns, shells, fuses, etc., are somewhat special, and for these stores the tolerances possible have to be fixed in each individual case, but there is a very large demand for bolts and nuts, studs, and the like, using in most cases the finer series of pitches, and experience soon showed that the tolerances fixed by the Committee were too small. These various factors led to a reconsideration of its decision, with the result that a new report on British Standard Fine Threads and their Tolerances, was issued in June last. Corresponding reports on the Standard Whitworth Series B.S.W. Threads, and the B.A. Threads are in course of preparation, and it is hoped will appear very shortly.

Form of Thread

The question of the form of the thread was considered with great care, and the Committee had the advantage of discussing the series of pitches and other points of importance with the American Commission on Standardization of Aircraft Parts. It was clear to all that without deciding on the merits of the case it was impossible under existing conditions to alter the B.S.F.

[1] Director of the National Physical Laboratory and Chairman of the Sub-Committee on Screw Threads of the British Engineering Standards Association.

For presentation at the Annual Meeting of The American Society of Mechanical Engineers, New York, December 3 to 6, 1918. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis by members upon application. All papers are subject to revision.

series of pitches, and it also appeared that provided the pitches were the same the 5 deg. difference in angle between the English and American threads would not prevent a very considerable degree of interchangeability. This conclusion has been substantiated by measurements since made on both sides of the Atlantic.

As to the form of thread, the evidence collected showed that, provided no close limits are placed on the exact curvature at crest and root, the rounded Whitworth form had distinct advantages from the manufacturing standpoint. The alteration suggested was the flattening of the crests in accordance with the theoretical Sellers thread. Further experience and measurement show distinctly that in practice the crests of American threads are frequently rounded, while it is agreed on all sides that rounding at the roots is essential to strength. Rounding at the roots is produced naturally by the wear of a sharp-pointed tool, and it appears probable that the radius selected by Whitworth (Radius $= 0.137\ p$, where p is the pitch) represents the stable condition reached by a pointed tool after some slight use.

Much the same is true at the crest; the difficulty of making a die with sharp corners that will stand wear is well recognized.

The Committee, therefore, decided to adhere to the Whitworth form, but without insisting on the exact curvature at crest and root so far as the work is concerned. In the case of a gage, however, their conclusion is that the theoretical form must be followed and attention given to the curvatures.

Tolerances on Form of Thread

It remained then to consider the tolerances. The measurement at the National Physical Laboratory of bolts and nuts made in the ordinary course of the work, and especially of aircraft and other similar parts, during recent years had afforded valuable information of the accuracy attained by manufacturers, as well as of that needed for interchangeability.

In dealing with tolerances it is convenient, whenever possible, to base them on a formula connecting them with the other dimensions on which they depend. For screw threads these are the pitch of the screw and the diameter of the cylinder on which it is cut—for a screw of given form the depth of the thread and the curvatures at crest and root are all proportional to the pitch. For the B.S.W. or B.S.F. series of bolts and nuts the pitch is definitely related to the diameter, and it appeared best to treat the tolerances as depending on the pitch only.

TABLE 1 BRITISH STANDARD WHITWORTH SCREW THREADS

Tolerances for Bolts

Nominal Diameter of Screw	No. of Threads per in.	Pitch	Tolerance on Pitch per in. length of Thread	Full Diameter			Effective Diameter			Core Diameter		
				Max.	Tolerance	Min.	Max. for a Screw of Correct Pitch	Tolerance	Min.	Max.	Tolerance	Min.
In.		In.	In.	In.	In.	In.	In.	In.	In.	In.	In.	In.
1/4 (0.25)	20	0.05000	0.0035	0.2500	0.0018	0.2482	0.2180	0.0018	0.2162	0.1860	0.0023	0.1837
1/2 (0.5)	12	0.08333	0.0030	0.5000	0.0025	0.4975	0.4466	0.0030	0.4436	0.3933	0.0032	0.3901
1	8	0.12500	0.0025	1.0000	0.0035	0.9965	0.9200	0.0050	0.9150	0.8399	0.0045	0.8354
2	4.5	0.22222	0.0021	2.0000	0.0050	1.9950	1.8577	0.0084	1.8493	1.7154	0.0064	1.7090
3	3.5	0.28571	0.0019	3.4000	0.0060	2.9940	2.8170	0.0114	2.8056	2.6341	0.0078	2.6263

Mr. Sears, Superintendent of the Metrology Department of the National Physical Laboratory, was able to show that tolerances proportional to $\sqrt{p}$, p being the pitch, agreed very closely with those found to work well in practice over a large series of pitches, certainly over the whole range covered by the B.S.F. and B.S.W. series, and indeed some way into the B.A. series. He showed further that the quantity $0.01\ \sqrt{p}$, p being measured in inches, was a convenient unit of tolerance, and that the tolerances suitable for the B.S.F. series were all given by some small multiple of this quantity. Accordingly, for ordinary work, the Committee has specified the tolerances given in Table 2, while for finer work a table of close fits, having half the above tolerances, has been adopted.

These tolerances are all negative on the bolt, positive on the nut, so that theoretically a bolt, if within the tolerances, should always pair with the corresponding nut, even if in the table of dimensions the maximum dimensions of the bolt are the same as the minimum dimensions of the nut, the dividing line being the theoretical form. But it is not possible to secure this in all cases. The gages used to test the work have their own tolerances, and are also subject to wear. To overcome these difficulties, an allowance of 2 mils is specified everywhere between the largest bolt and the smallest nut.

It seems probable that in the case of the close fits this will need reconsideration; for many purposes it is more important to secure a tight fit than to have complete interchangeability among a large series of bolts and nuts, and, with the figures given in the table, when the maximum nut is paired with the minimum bolt, and the pitches and angles of the two happen to be identical, the fit will be a slack one.

Tolerances in Pitch and Angle

It will be noted that the tables do not specify tolerances in pitch and angle; it has been pointed out already that in the case of a bolt an error in pitch can be compensated by a reduction of effective diameter of approximately twice the total pitch error; an error in angle can be compensated in the same manner. It is a necessary condition then for a bolt that the total reduction in effective diameter required to compensate the errors of pitch and angle must never exceed the permissable tolerance on effective diameter; a similar condition holds for a nut.

A simple graphical method of calculating the effective diameter equivalents of the pitch and angle errors has been devised by Captain Bishop, while a simple mechanism for applying Captain Bishop's method has been developed at the National Physical Laboratory. Denoting by x the effective diameter error, y and z the effective diameter equivalents of the pitch and angle errors, Captain Bishop introduced the term "grade" to denote $x+y+z$, the sum of these three; it will be found to measure the difference in diameter between the standard nut and a bolt of standard form which would just pair with a nut of the same dimensions as the bolt in question; the play, meaning thereby the lateral shake between the given bolt and a standard nut, is measured

TABLE 2 TOLERANCES IN TERMS OF PITCH

	Full Diameter	Effective Diameter	Core Diameter
Bolt........	$3 \times .01\sqrt{p}$	$2 \times .01\sqrt{p}$	$4 \times .01\sqrt{p}$
Nut........	$4 \times .01\sqrt{p}$	$2 \times .01\sqrt{p}$	$3 \times .01\sqrt{p}$

by $x-(y+z)$. For some purposes it is found convenient to specify screws by their grade and play. The grade indicates in a general way the difference between the bolt and the standard; the play gives a measure of the slackness of fit.

It has been pointed out already that the pitch error with which we are concerned is not the error per pitch or per unit length, but the total error in the length of thread engaged; the error per pitch which is permissible then will depend on the number of threads engaged, and the manufacturer who desires to know whether a tool cutting threads with some definite errors per pitch will cut a screw up to the specification, requires also to know the length of thread engaged. The Committee are now engaged on a series of tables which will give the corrections in effective diameter required to compensate pitch and angle error.

Gages and Gaging

The importance and difficulty of the question of gages and gaging have been before the Committee almost since its inception, and the principles on which it depends have been often stated.

The gaging of plain cylindrical surfaces is a simple matter; to gage a ring a go and a not-go plug suffice; for a shaft we need either go and not-go rings, or go and not-go snap gages. But for a complicated form like that of a screw, the matter is far from simple; the screw is made up of many elements, and each needs separate consideration. A little investigation shows, however, that for exact work the go gage must gage all the elements simultaneously, while each element requires a separate not-go gage. Thus, for a screw there are seven elements: Full diameter, core diameter, effective diameter, pitch, angle of thread, radius at crest, radius at root.

In symmetrical threads like the Whitworth, the last two elements are the same. The go gage insures that the work nowhere oversteps the theoretical boundary; the not-go gages confine the tolerances on the various elements within the specified values. If interchangeability alone is to be gaged, and a more exact knowledge of the errors of the various elements is not required, the not-go gages can usually be reduced to the first three. The form at root and crest is immaterial, provided the full and core diameters are not too greatly reduced: The go gage insures that the standard boundary is nowhere overstepped. The go gage also insures that the reduction in effective diameter has been sufficient to compensate the errors, if any, in pitch and angle, while the not-go effective-diameter gage provides that the effective diameter is not less than is tolerated in the tables. Thus, a complete go gage and three not-go diameter gages are needed.

It is easy to provide gages for the full and core diameters: In the case of plugs a simple ring, or a suitable snap gage, suffices; for nuts a plain cylindrical plug gages the core diameter; the full diameter is tested by a screw gage having one or two turns, with a very thin thread arranged to bear on the full diameter only. The effective diameter of a nut can be gaged by a screw plug of one or two turns, cleared at the roots, and with the crests ground off so as to bear only on the slopes of the threads; while for the effective diameter of a plug a ring gage bearing only on the slopes is available. A design of effective-diameter gage which is satisfactory and not too complicated has not, however, been found as yet, and the Committee are still giving the matter careful consideration. One of the difficulties is that of inserting the gage: an incorrect thread on a piece of work may be burred or contracted at the end at which the gage enters; it rejects the gage and is apparently correct, whereas had the gage passed the obstruction it would easily also pass the whole of the rest of the screw, which should therefore fail. To overcome this, various forms of expanding gages are under trial at present. The fact that it is necessary for the go gage to be complete in all its elements adds greatly to the difficulty of making gages. It is sometimes suggested that in the case of a ring gage used for bolts it is sufficient to clear the gage at the roots of the thread, and check the full diameter of the work with an ordinary ring gage. In the case of the Whitworth thread with rounded crests this is inadmissible for two reasons: (1) There is no security that the work in the neighborhood of the crest does not overstep the theoretical shape, and in this case it would not enter a nut of correct dimensions, and (2) there is no means of determining the concentricity of the various parts of the thread.

In the case of a flat-topped thread, the first difficulty does not occur; provided the parts of the thread are concentric the two gages give the necessary boundary exactly, but the second difficulty still holds. Concentricity can only be tested by a gage of complete form, and the construction of such a ring gage with flat roots is more difficult than that of one with the roots rounded to the Whitworth curvature.

Methods of gaging such as have been described are practicable enough when dealing with a limited amount of work; they become tedious, and, so far as effective diameter is concerned, not very satisfactory when dealing with masses of stores as in munitions work or the ordinary commercial supply of nuts and bolts. For bolts a method of gaging by projecting the image of the work on to a screen carrying an accurate magnified drawing of the screw under test has proved rapid and effective, and apparatus for this is in use in many factories.

Another method consists in keeping a careful watch on the tools employed, being assured that so long as they remain correct within certain limits the work they turn out will come up to specification. Most valuable work in this direction is being done by the Panel on Taps Sub-Committee, which is investigating the methods of measuring taps, the conditions that connect the size of a tap and that of the hole it taps, the limits within which taps must lie in order to give specified results and the like, and in due time the result of the work will be available. The Panel will also deal with dies and chasers.

Tolerances on Gages

Another series of questions is raised by the consideration of the tolerances to be allowed on gages; as a rough rule we expect these to be from 1/5 to 1/10 of the tolerances on the work. Their sign, however, depends on the purpose for which the gage is required.

Six classes of gages are recognized:

Standard gages, for depositing with a recognized authority; reference gages, for use by manufacturers; inspection gages, used by inspectors to check the accuracy of the work and determine if it is within the limits laid down; shop gages, used in the workshop to control manufacture; check gages, for verifying the accuracy of other gages; and master gages, used only in the manufacture of, or for the purpose of verifying, check gages.

Testing and Measuring Gages

The demand for munitions gages has led during the past few years to an important development of the methods of testing and measuring gages.

Until recently gages of all kinds have been dealt with at the National Physical Laboratory at the rate of about 10,000 a week; at present over 2,000 screw gages are being tested weekly.

Machines have been devised at the Laboratory for the rapid performance of the measurements required. In the case of a plug gage the diameters and pitch are all measured in suitable machines, the form of the thread is examined in a projection apparatus and the concentricity is tested by the use of a complete ring gage.

For a ring gage the diameters are checked by suitable go and not-go gages, the pitch is measured and the form is verified by taking a cast and examining it in the projection apparatus.

Through the coöperation of the industrial power plants which have thus far put into force the standard recommendations of the United States Fuel Administration to promote efficiency in the use of fuel, a saving of 7,000,000 tons annually has been effected. That is to say, in the first six months from the announcement of the national program, 3,500,000 tons have been conserved, at the same time maintaining maximum production in the factories. The largest savings have been in Massachusetts, Pennsylvania, Connecticut, Illinois and New York.—*Power*, Nov. 12, 1918.

PRESENT PRACTICE IN THREAD-GAGE MAKING

By FRANK O. WELLS,[1] GREENFIELD, MASS.

THE manufacture of thread gages brings in all the difficulties of any thread product, multiplied according to the degree of accuracy required. The usual methods of making threads must therefore be refined and improved, and at the same time standardized for manufacturing purposes.

Correcting Lead Screw

Given the blank for a thread plug gage, centered and turned, the real trouble begins with chasing the thread. A lead screw should be as accurate as the product to be turned out by it. Errors in lead screws are of two kinds—errors in lead over a considerable length of the screw, and local errors from thread to thread. If, as is often the case, the lead screw was made for ordinary work instead of for precision work, its lead or pitch will

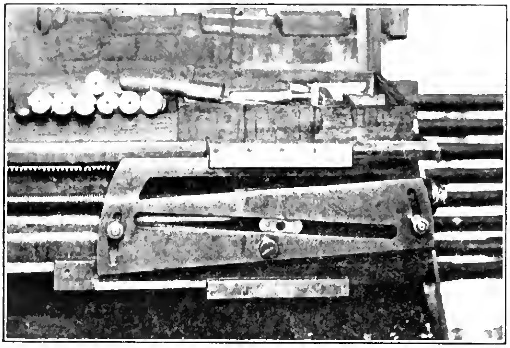

Fig. 1 Lead-Adjusting Attachment for Lathe

be irregular to a greater or less extent. The total deviation of the lead screw must then be determined, and the lead-adjusting attachment (Fig. 1), set to give the correct compensation.

The thread cut on a soft gage must always be slightly different from standard or finished pitch, by an amount equal to the expected change during hardening. This correction must also be made by the lead variator.

Adjusting attachments like that in Fig. 1 compensate fairly well for errors in the lead screw which are constant at any part of its length. They do not, however, take care of the trouble of "high and low" threads. In lathes used for thread-gage chasing the lead screw ought to be as perfect as possible from thread to thread and the ways of the lathe should be scraped accurately parallel and level so that the head and tail centers will be in line.

Chasing Tools

Given a fairly good lead screw, the next mechanical necessity is a good cutting tool correctly held. Such tools, with removable cutting blades, are shown in Figs. 2 and 3, one for inside and the other for outside chasing. It is a question whether a single cutting tool or a multiple-toothed chasing tool is better for this work.

The threading-tool blades in Figs. 2 and 3 are made to cut on a 20-deg. clearance angle. This clearance angle makes the actual included angle of the tool blade, normal to the straight cutting edge of the tool blade, 63 deg. and 8 min. The thread groove cut by a proper threading tool should preferably be from 15 to 30 min. sharp in order to facilitate the lapping operation. For all ordinary U. S. standard pitches the threading tool blade is set with its axis at right angles to the axis of the gage. It is only for Acme or similar very coarse thread work that it is necessary to incline the threading blade to a line parallel to the helix angle of the gage being threaded. When this helix angle is very steep it is necessary to modify the included angle of the cutting edge so that the angle cut, on a plane with the axis of the gage, will be as required by specifications.

A clearance channel is universally acknowledged desirable in a thread gage so that no chips lodging in the gage will bind between the gage and the thread crest of the tested thread and give a mistaken impression of a close fit.

There is great difficulty in getting men who are good at threading. Good threaders seem to be born, not made. The work requires a combination of brain, mechanical ability, sensitive touch, and above all, patience. Some otherwise good mechanics can never make good threaders. A green man with a phlegmatic temperament is a likely candidate for development. Few girls can be developed into handling fine threading—it requires just a little more mechanical sense than any appreciable number have had time to acquire.

With good men, fair lathes, the best cutting tools and the exercise of constant care, it is possible to get threading of gages

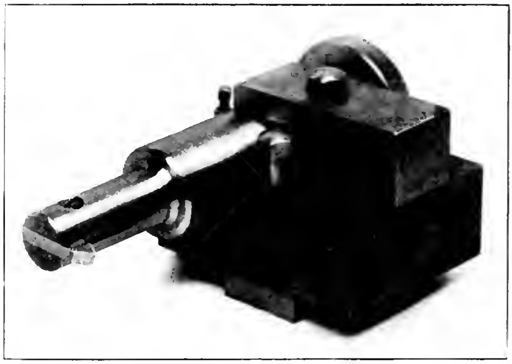

Fig. 2 Tool for Inside Chasing

down to a limit of accuracy which falls within the variations due to hardening. If a perfect contour of thread, and perfect angle, lead and walls could be secured when threading in a lathe, it would not be necessary to leave more than 0.0002 to 0.0006 in. oversize, knowing that hardening would increase this to from 0.0015 to 0.0020 in. Due to irregular swelling, shrinking and warping from thread to thread in the hardening, however, a certain amount of stock must be left on so that no point of the gage shall be distorted outside of the limits of the metal. If the thread, for instance, should take a quirk to the right so that its center line was displaced at the top of the crest by 0.0009 in., and the metal had been left 0.0015 in. larger than finished size, the reduction to finish could be made and still leave a complete crest.

Since a margin must be left for the vagaries of hardening, the necessary tolerance in lathe threading can probably be obtained by the precautions noted.

Formerly it was common practice to make the outside diameter of limit plug thread gages uniformly oversize in direct proportion to the oversize of pitch diameter. This practice was wrong because of the danger of the maximum or no-go plug forming contact on the outside diameter of the tapped hole and yet giving no indication as to the actual size of hole on the pitch diameter or the thread walls.

In view of the fact that both the go and no-go plugs are over

[1] President, Greenfield Tap & Die Corp.; Mem. Congressional Screw-Thread Commission; Mem. Am. Soc. M. E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application.

basic or maximum screw size, they should both be provided with a minus tolerance below the minimum tapped-hole outside diameter, in order to assure that the gage will positively check the angular diameter. This can be done since there is no danger of the screw forming contact with the outside diameter of the tapped hole.

Hardening

The hardening question has always been the bane of threading. A series of tests made sometime ago by laboratories of manufacturing firms throughout the country demonstrated that threading on taps and dies can be gotten down to any reasonable limit of accuracy, but that this is not true of hardening. The inaccuracies in taps and dies, manufactured as is necessary by quantity methods, in general appear after hardening and are not present in the soft product. The same is true of gage threads, only of course the error involved is proportionally of more importance on such fine work.

During the process of hardening there is in the majority of cases an increase or swelling in diameter and a shrinkage in length, resulting in a shortening of lead, but the extent to which this occurs will vary in different pieces. Even with the quenching bath and the temperature of furnace kept uniform, the swelling in diameter in one set of duplicate samples of about an inch in diameter varied from 0.0008 to 0.0024 in., and the lead error varied from 0.0005 to 0.0025 in.

The only way to control this is to find a heat treatment and a quenching bath which will always give the same expansion and contraction under standardized methods of working and dipping, then see that the handling methods actually are standardized. And not only must uniform handling methods be followed, but the steel must be of uniform quality. For this reason it is necessary to have a supply of steel from which any piece may be taken and relied upon to act like every other piece. If such steel cannot be secured from the steel men, it is advisable to get the most uniform brand available and then standardize it still more by heat treatment.

Lapping

If the lathe work has been done correctly and the hardening without distortion the thread can be smoothed to a finish by lapping off not much more than 0.0002 in. Under ideal conditions, therefore, this would be the amount of oversize that would be specified for gages coming into the lapping room. A much neater and quicker job of cleaning the thread to size could then be done, and the cost of lapping would go down.

However, not only excessive oversizes but distorted pieces come into the lapping room. The lapping process can to a certain extent take out these inequalities as well as smooth the surface of the chased thread. It should be emphasized, however, that the lapping process is not for this purpose and that every correction that has to be made in the lapping costs excessively and slows up the other work. Lapping should not be depended upon to do correcting, but the threading should be in correct shape before reaching the lapping room.

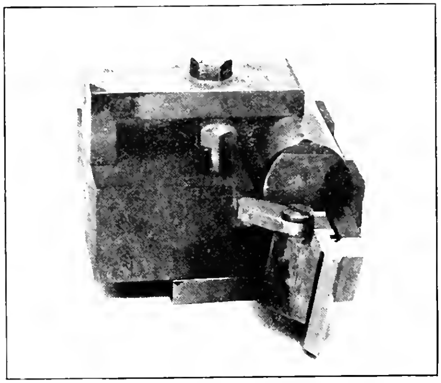

Fig. 3 Tool for Outside Chasing

If the angle of the thread is slightly too wide or narrow or tipped to one side, a skillful lapper can correct it. If the lead is a trifle too long or short, the lap can take it back to the proper length, by wearing the surface off on one side or the other of each thread. If the pitch diameter is too large, it can be worn down. But, of course, there is a limit to the amount that can be worn off by hand-applied friction, using the general form of thread as a guide, and still retain an accurate contour. It is practicable to take off a total of 0.0015 in. by lapping without spoiling the shape, if it is done carefully on only one gage. Therefore, allowing part of the overstock for smoothing, if the errors are not cumulative or all in the same direction, it is possible in lapping out 0.0015 in. oversize in diameter, to take care of an error of 0.0005 in. in lead and an error of 15 min. one way or the other in the angle.

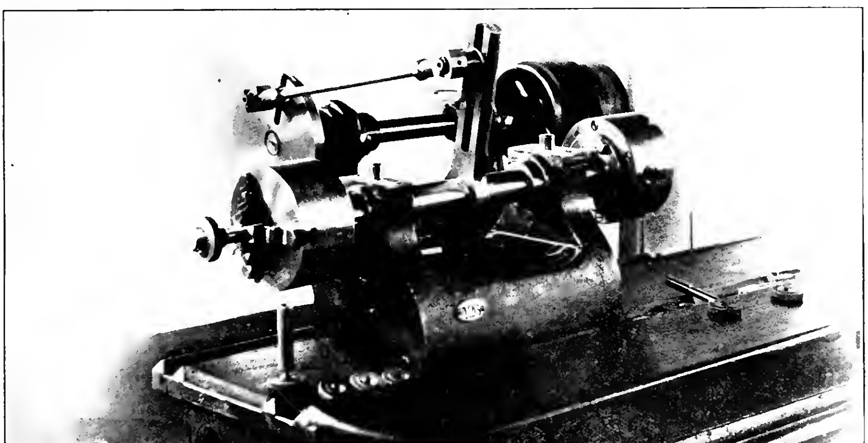

Fig. 4 Double Lapping Machine

Two forms of lapping machine for thread plug gages are

shown. In the best plug-lapping machines the plug is mechanically rocked back and forth through a fraction of a revolution, while the operative holds the lap still in one hand, encircling the plug. threaded more accurately than the gage which it is to correct. Flour of emery makes the most satisfactory lapping medium for thread gages, particularly for lapping the thread walls. Fifteen-

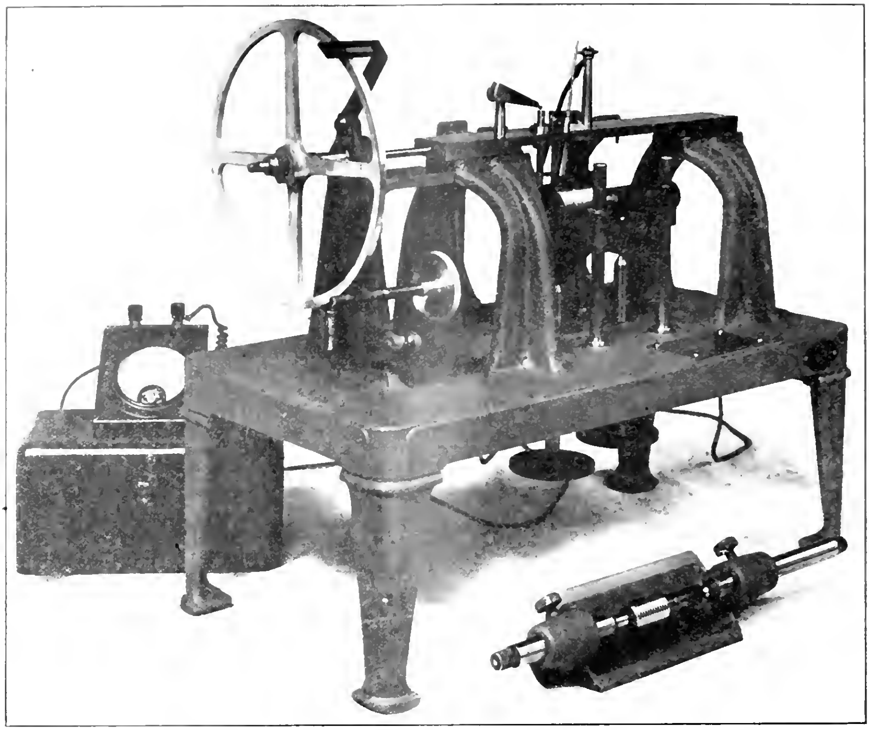

FIG. 5 BINGHAM POWELL LEAD-TESTING MACHINE

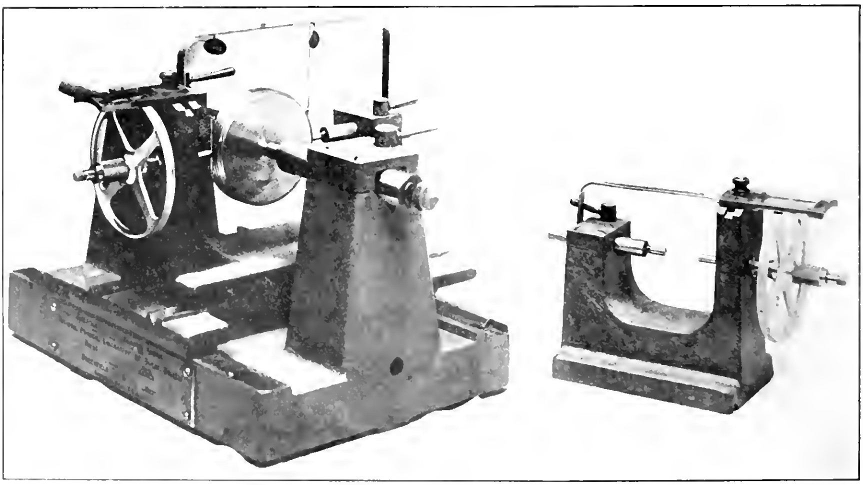

FIG. 6 MACHINE FOR TESTING PITCH

Since the operative might as well be using both hands, a double ended machine is provided, shown in Fig. 4.

Soft steel laps are most easily chased out smoothly and are the most durable. Some prefer cast-iron laps, however. The lap is an important part of the work; it must, of course, be

minute carborundum is satisfactory for lapping outside diameters. Sperm oil makes the most satisfactory medium for carrying the abrasive, chiefly because of its non-gumming quality and because at the same time it has more body than kerosene, which is quite commonly used.

Grinding Threads

Grinding out the inaccuracies in the larger-size threads is much more expeditious and cheaper than lapping them out. The problem of grinding threads becomes difficult, costly and impracticable, however, below a certain minimum size, in general, for the following reasons:

In grinding out a V-thread as near as practicable down to the theoretical triangular point, as is done in thread gages, there is intensified friction upon the delicate edge of the wheel and it wears away very quickly. It could not be used at all, were it not for the fact that the extreme edge of the wheel does not have to be maintained absolutely as an acute angle. On all practicable manufactured screw threads upon which the gage is to be used, whether U. S. S., International or Whitworth, at least the top eighth of crest is flattened or rounded off. Therefore, although the profile of the gage thread must be kept accurately straight along seven-eighths of the wall, the remaining eighth in the extreme root can be allowed to become a little rounded off, since it will not engage any part of the thread but will be used as a clearance space.

Now an eighth of a large pitch on a large diameter gives the wheel edge considerable margin for wear. The absolute length of this margin decreases toward the point in proportion as the pitch from thread to thread decreases, and soon the point is reached where the allowable eighth margin at the edge of the wheel wears away too fast for practicable replacement of wheels. One wheel should do at least one complete gage before needing to be trued at all, since the wheel cannot be taken out and put back in the same place with any success. This margin of wear on the wheel is now generally reached at a pitch of 16 threads to the inch, so that most gages below 5 16 in. pitch diameter have at present to be lapped out instead of ground.

There are other difficulties in the way of grinding small threads. On the average, the best thread-grinding wheel is about No. 150.H, as we find in our own work. For the grinding process, from 0.003 in. to 0.008 in. of stock should be left on a thread gage to enable the operative to set his wheel in the center of the thread by adjustment and trial, and also permit him to correct inequalities in lead, angle, or diameter due to hardening.

Out of 0.003 in. of stock he can increase or decrease the lead by 0.001 in., if the angle is already correct. Similar corrections in the other dimensions may be effected.

Work coming from the grinding room is then lapped smooth before it goes to the inspection room.

Inspection

Inspection in gage manufacture assumes an importance that it has in hardly any other branch of work. This is still more true of thread gages. The many dimensions that are on an apparently simple product require close attention to each separately and to all together.

To test the lead the Bingham Powell machine is a good instrument. The method of holding the gage, the micrometer wheel and vernier and the electric telltale which indicates proper contact of the measuring fingers and the thread, are shown in Fig. 5.

A testing machine fitted up with a slide rest in parallel so that only two wires are necessary is good for measuring pitch diameter, by aid of a micrometer reading. This machine is provided with two removable tables, one for large work and one for small, as shown in Fig. 6. To test the micrometer a set of Johansson blocks should be on hand, and finally to resolve immediately any doubts one might have as to the accuracy of a particular block or measurement, a good measuring machine should be on hand.

To examine the contour of the thread, the angle and the root, crest, and smoothness of wall, a projection machine as shown in Fig. 7, is the only proper thing. It instantly gives an enlarged silhouette of the thread, which speaks for itself, for the profile can be compared with pattern gages held upon the screen as in the illustration. The silhouette can also be photographed for transmission to a customer, by inserting a film or plate instead of the ground glass. Mechanism is provided for holding the gage, for focusing it and for turning it to the helix angle so as to get a symmetrical projection of the walls.

Sulphur casts of female threads can be taken in quick time and at small cost, and the contour examined in the same quick way. The method of pouring the melted sulphur into a molding frame held against part of the thread so as to get enough of it to give contour and lead, is shown in the complete paper.

Tolerance on Gages

One great difficulty with the business of manufacturing thread gages is the unreasonable and useless accuracy of gage tolerance and wear allowance sometimes requested by purchasing firms. When a tolerance of 0.0002 in. is set on a gage specification, it should mean that the customer's tolerance on product is as close as 0.001 in. If the purchaser's manufacturing tolerance is any broader than that, there is no use in keeping the gage so close.

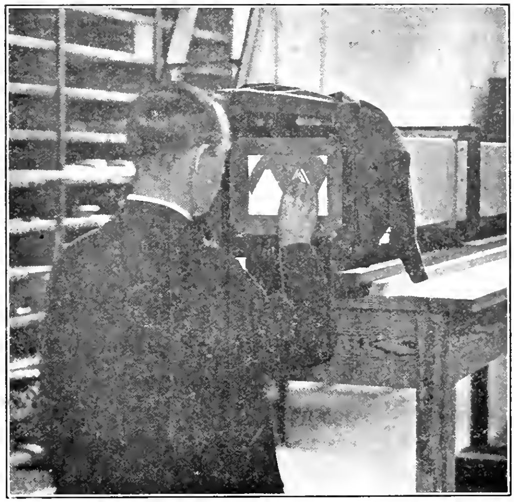

Fig. 7 Projection Machine for Checking Contour of Thread

A 0.0002 in. error would be lost in the comparison. In order to facilitate the making and to lessen the cost of thread gages, it is well to allow quite liberal tolerances in their manufacture, and we recommend the following as being applicable for most cases where medium tolerances are allowed on product:

From 4 to 6 pitch allow a tolerance of 0.0006 in.; from 7 to 18 pitch allow a tolerance of 0.0004 in.; from 20 to 28 pitch allow a tolerance of 0.0003 in.; from 30 to 80 pitch allow a tolerance of 0.0002 in.

The foregoing applies to master gages. For inspection gages the tolerances would be slightly wider, and would begin where the master inspection gage tolerances leave off. These would be as follows:

From 4 to 6 pitch a tolerance of 0.0009 in.; from 7 to 10 pitch a tolerance of 0.0006 in.; from 11 to 18 pitch a tolerance of 0.0004 in.; from 20 to 28 pitch a tolerance of 0.0003 in.; from 30 to 40 pitch a tolerance of 0.0003 in.; from 44 to 80 pitch, 0.0002 in.

All of the foregoing tolerances would be applied plus in the case of go male gages and no-go female gages; and minus on no-go male and go female thread gages.

The plus and minus tolerances given apply to pitch diameters of all thread gages and also to root or core dies of templets or female thread gages.

The maximum, or go, templet gage represents the maximum or basic screw and its manufacturing tolerances should be minus on pitch diameter and root diameter. The minimum, or no-go, templet should be made to plus tolerances with an extra plus allowance on the root diameter, which will insure this gage's really checking the effective size of the screw. The wear and adjustment tolerance on a gage should be coarse or fine on a sliding scale according to the manufacturer's tolerance on his product.

STANDARDS FOR LARGE TAPER SHANKS AND SOCKETS

By LUTHER D. BURLINGAME,[1] PROVIDENCE, R. I.

WAR needs have demanded the construction of machine tools embodying taper shanks and sockets of larger dimensions than it has been customary to build them. Most of the tapers established in the early days before the question of standardization was given much attention, present irregular variations in size and in depth, even within the same system, as will be noticed by observing the figures given in Table 1, where the most widely used tapers are described. The application to the large sizes of the rules followed in proportioning these early types, does not give the dimensions required to meet the new conditions.

The problem of working out a standard for the large sizes necessitated by present exigences was presented to the Brown & Sharpe Mfg. Co., and after an extended investigation and study of the conditions to be met, it has arrived at the tentative form described in this paper. The choice was based on a study and analysis of present established tapers, an investigation of the laws governing the use of tapers and a referendum of experience and opinion from a number of manufacturers and engineers who, because of their close contact with conditions most nearly like those desired to be met, it was felt would best be able to judge of the requirements.

TABLE 1 DATA ON TAPERS IN GENERAL USE

Taper per ft., in.	Included Angle	Ratio	Name	About when introduced	Where Used
½	2° 23′	1:24	Brown&Sharpe	1860	Milling machines and general
6/10	2° 52′	1:20	Jarno	1889	Reed lathes, Pratt & Whitney machines, etc.[1]
⅝	.	1:19⅕	Morse	1862	Twist drills, drill presses, etc.
¾	3° 35′	1:16	Sellers	1862	Lathes, boring machines, milling machines, etc.

1½	7° 9′	1: 8	Muir (England)	......	Milling machines, "patent couplings" for arbors

[1] Also since used for German metric tapers.

Taper per Foot

As shown in Table 1, the well-established tapers for shanks and sockets now in use vary from ½ in. to 1 in. or more per ft., the tendency being to use a somewhat steeper taper for the larger than for the small sizes, perhaps because with small tapers, the liability to slip produced by the work is not so great and the "bite" of the taper when forced into the socket is sufficient to secure effective driving. In the larger sizes, tenons or tongues must be provided to aid in driving, and in the still larger sizes keys of some form are needed, as, unless the angle of taper is very slight, the tenons are liable to be twisted off. When such auxiliary means of driving is provided the taper can be made steeper, giving the advantage that the parts can be more easily separated.

An illustration of the use of a greater taper per foot for large as compared with small sizes is found in the "old American taper" having 9/16 in. taper per ft. up to the size 1 in. in diameter at the small end, beyond which the taper became ⅝ in. per ft.

An extreme application in the direction of steep tapers is in the arbor couplings used for milling-machine arbors, made by Wm. Muir & Co., Ltd., of England. These arbors are drawn into and removed from the socket by means of differential-threaded nuts, the taper being 1½ in. per ft.

On the other hand, tapers as slight as ½ in. per ft. have given satisfactory results in milling machines and other machine tools, where they have been in constant use for at least the last sixty years. The "bite" on the small sizes is sufficient, when driven in place, to hold without working loose under jar, while the angle is not so small as to prevent driving apart when desired. It is found, however, that occasionally a taper of ½ in. per ft. will stick so tightly as to require considerable force to separate the parts, perhaps in such cases as where a cold arbor is driven into a heated spindle. With a taper as slight as ½ in. per ft. there is seldom trouble from having the tenon twist off, as is so often the case with twist drills made with a taper of approximately ⅝ in. per ft., and where on account of the greater taper the "bite" of the taper fit does not carry so great a proportion of the load.

[1] Industrial Superintendent, Brown & Sharpe Mfg. Co., Mem.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

Principles on Which Tapers Depend

Oscar J. Beale of the Brown & Sharpe Mfg. Co., originator of the "Jarno" taper, made an investigation of the principles on which the taper of shanks and sockets should be proportioned, and published his findings in the *American Machinist* of October 31, 1889, p. 3. His analysis is a clear statement of conditions governing the taper per foot.

After asking, "Is there a scientific principle involved in establishing a taper?" he answers: "There is this principle, that the angle of the taper must not be so large that a center will not stay when driven in and that the angle need not be so small as to make it very difficult to back the center out," and after illustrating by means of a diagram he continues: "The average angle of repose in metals having smooth surfaces that are oiled is placed by Unwin at 4½ deg. and by Willis at 5 deg. Rankine gives an angle the same as or a little smaller than Unwin and adds that in some experiments the angle has been as small as 2 deg." From or other tapers with a less steep taper in the ease with which it will release when it is desired to drive it out. Further, it is a taper which apparently is now in most general use for large work, although its proportions, as far as the writer knows, have not previously been standardized.

The taper of ¾ in. per ft. was adopted by William Sellers & Co., Inc., of Philadelphia, about 1862, when they abandoned the flattened end or tenon and adopted a key fitting lengthwise of the taper for driving, rather than to depend largely upon the "bite" of the taper for that purpose.

William H. Thorne, in a paper[1] on Twist Drills presented before The American Society of Mechanical Engineers in 1885, after pointing out the objections to driving by a tongue as is the usual practice in using twist drills, says:

> A far better device is a key, fitted permanently into the sockets, and extended the entire depth of the latter. This key fits a groove in the shank of the drill, and supplies a perfect means of driving the latter, with a minimum of wear and strain. The end of the shank for a short distance is turned smaller, and is hardened to prevent any upsetting by the use of a drift or wedge in removing the drill. The amount of taper proper for the shank is a disputed question. The Morse taper averages less than ⅝ in. in diameter per ft., but with drills driven by means of a key ¾ in. per ft. is better as it enables the drills to be more readily removed from the sockets, and at the same time prevents them from falling out by their own weight.

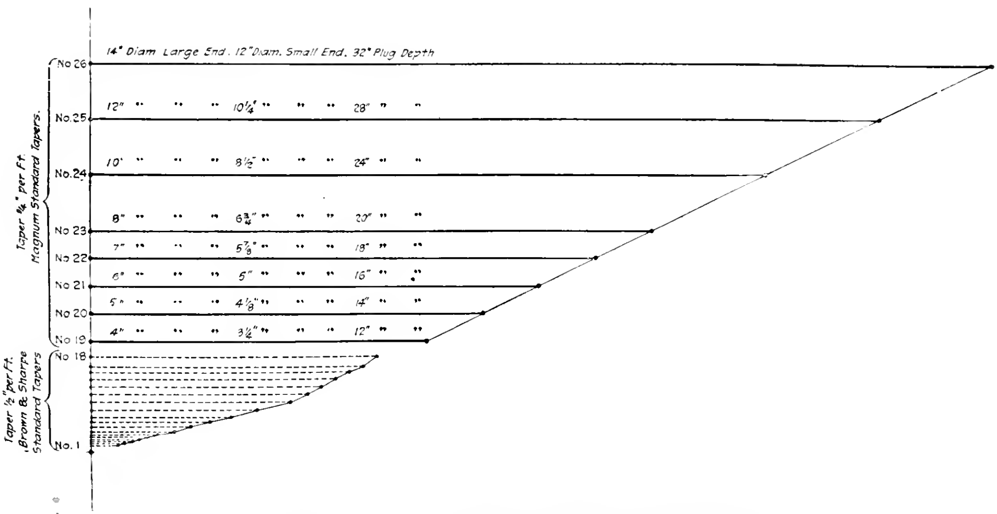

Fig. 1 Relation of Proposed Standard Taper Lengths to Established Brown & Sharpe Sizes

a further demonstration Mr. Beale concludes, regarding tapers, that if the angle must be such as to permit slipping, it should be as great as 10 deg., while if it should not permit slipping, it should be less than 4 deg. Also:

> If a center be of a taper whose sides make an angle of less than 4 deg., it is not likely to slip out, after being driven in, even though it be oiled. An angle of 4 deg. makes a taper of nearly ⅞ in. per ft. No center, so far as I have seen, has a taper greater than this, which is interesting as indicating that the machinist, in practice, has not exceeded the angle of safety given in the textbooks. . . . The smallest center angle that I know is something less than 2½ deg., which in practice has been found to be small enough. We are therefore at liberty to choose any angle of taper between 2 and 4 deg.

Mr. Beale chose for the Jarno taper, 0.6 in. taper per ft. (2 deg. 52 min.) as an average between these limits. This gives a ratio of 1 in 20, a ratio which has since been adopted for the German metric standard and is especially adapted for use with a decimal system of measurement. In applying it to the English system of measurement, however, it gives the dimension at one end of the taper in tenths and at the other end in eighths, a feature which, while not especially objectionable, lacks the advantage derived from using the taper of ¾ in. per ft., which gives, with each inch of depth, $\frac{5}{16}$ in. variation in diameter, so that when applied to large tapers, whose depth may be made to vary by 2 in. or 4 in., the diameter at both large and small ends come in whole or convenient fractional sizes.

A taper of ¾ in. per ft. also gives an advantage over 0.6-in.

Mr. George R. Stetson, in discussing Mr. Thorne's paper, said:

> The objection to a sharper angle or taper is that the drill has a tendency to draw out of the socket when coming through its work. This twists the tongue and produces most of the trouble complained of and would be best obviated by a taper of less than ⅝ in. to the foot.

What applies to the use of tapers for drills in this discussion applies in general to the use of tapers for sockets and shanks, and the conclusion can be drawn that if the "bite" of the shank is to be depended on to a considerable extent to do the driving, the taper should be small, even at the risk of finding occasional difficulty in separating the parts.

On the other hand, if adequate means of driving is to be provided in addition to the "bite" of the taper, there are advantages in making the taper greater, although not so great as to allow of jarring loose or dropping out readily.

Assuming that in all cases of machine tools using these large tapers either longitudinal or cross-hold-back keys or both will be

[1] Trans., Vol. 7, p. 132.

used for driving them, a greater taper per foot can be used, thus obtaining the advantage of easy removal with no sacrifice in driving efficiency. To meet these conditions, a taper of ¾ in. per ft. for large sizes seems ideal, based on scientific grounds and also on the experience of users.

Lengths for Tapers

While the length can be more elastic, a variation being less objectionable than in the case of the diameter or taper per foot, it is desirable to standardize it also. As previously pointed out, the tapers already established do not give proportions for lengths suited to large sizes. Thus the Jarno formula would make a taper of 14 in. in diameter at the large end, 56 in. long—much too long for practical needs and adding an excessive amount to the cost of both gages and reamers as well as of the machine. A proportion used by some Philadelphia manufacturers who have made the depth three times the diameter for moderately large sizes, is admitted by them to be probably longer than necessary even for these sizes. Such a proportion would make the above 14-in. taper 42 in. long.

The Proposed Standard

By the use of a constant, a formula has been derived applicable over a wide range, and giving, it is believed, satisfactory proportions. Fig. 1 illustrates the relation of the proposed taper standard for length as derived from this formula, to the established Brown & Sharpe sizes, showing that these new tapers follow in a regular progression beyond the largest established Brown & Sharpe sizes.

As a result of this investigation the sizes in Table 2 are proposed, to be known as Magnum Standard Tapers.

The reason for beginning the numbering at 19 is to avoid lapping on to the numbers of any of the systems now in use, No. 18 of the B. & S. standard being, so far as known, the largest standard as yet suggested. No. 19 of the new system is proportionately larger than the B. & S. No. 18, so that, starting with No. 19 seems logical, even though the new standard has a different name and is of a different taper per foot than the old.

It will be noted that the diameters at the large end are made basic and vary by inches, and with the length of taper obtained by the formula the diameters at the small end are in convenient fractional sizes.

Before determining on the proportions of the Magnum tapers the question of the proportions of large standard tapers was taken up with manufacturers and engineers having experience along these lines. Table 3 gives a digest of the opinions received from various sources in answer to the writer's inquiry as to their past experience with large tapers.

DETERMINATION OF STRESSES IN WIRE ROPE AS APPLIED TO MODERN ENGINEERING PROBLEMS

By JAMES F. HOWE,[1] WORCESTER, MASS.

THE consideration of stresses in wire rope necessitates the consideration of this problem from a broad standpoint so that each factor governing the action of wire rope will be fully understood. The structure of wire rope is such that axial compressive stresses need not be considered, only those allied to tension or bending requiring study. The first problem to be considered and the one upon which all stresses depend, is the determination of the strength of strands and ropes.

Strengths of Strands and Ropes

In constructing a wire rope a number of wires arranged according to some definite geometrical cross-section are twisted with a uniform pitch or lay into what is technically known as a strand. The object of twisting the wires into strands and strands into rope is to bind the wires compactly together and to increase the flexibility of the wire rope. Both the wires composing the strands and the strands composing the rope are twisted and laid up so that there is no torsion in either the wires or strands.

While stranding increases flexibility, it is not accomplished without some loss in strength due to twisting. It is obvious for comparative purposes that the strength of a straight wire may be taken as unity or 100 per cent. Strands are usually made of 7, 19, 37, 61, etc., wires, and ropes of six strands (occasionally eight). When a number of wires are twisted together around a central wire, they make an angle with the central wire or axis. The shorter the twist the greater the flexibility, but at the same time the strength is decreased proportionately. This will be understood from Fig. 1.

A wire with a strength S in a strand will have a component strength T along the axis of the strand, or

$$T = S \cos \theta$$

where

θ = angle of helix of wire in the strand.

Also, if

D_p = pitch diameter of strand

n = lay divided by pitch diameter of wires

d = diameter of wire in strand (assuming all wires the same size)

c = constant by which wire diameter is multiplied to produce pitch diameter

$$\text{Pitch circumference} = \pi c d \text{ and Lay} = nD_p \ldots\ldots [1]$$

In the case of a seven-wire strand, the center wire being straight, the total strength of strand W_s is obviously

$$W_s = S + 6S \cos \theta = S(1 + 6 \cos \theta) \ldots\ldots [2]$$

If θ_1, θ_2, θ_3, etc., represent the angle of the helix of successive layers of wires in a symmetrical concentric strand for layers of 12, 18, 24, etc., wires,

$$W_s = S + 6 \cos \theta + 12 S \cos \theta_1 + 18 S \cos \theta_2 + 24 S \cos \theta_3 + \text{etc.,}$$
$$= S(1 + 6 \cos \theta + 12 \cos \theta_1 + 18 \cos \theta_2 + 24 \cos \theta_3 + \text{etc.}) \ldots [3]$$

If the angles θ, θ_1, θ_2, etc., are equal the equation becomes

$$W = s [1 + (N - 1) \cos \theta] \ldots\ldots [4]$$

where N = number of wires in strand.

Similarly in a rope,

let W_r = strength of rope with hemp center

Y = angle of strands in rope (assuming 1 layer of strands such as 6 or 8)

N_1 = number of strands in rope.

The strand strength W_s must be applied in just the same manner as before, and

$$W_r = W_s N_1 \cos Y \ldots\ldots [5]$$
$$= SN_1 \cos Y [1 + (N - 1) \cos \theta] \ldots\ldots [6]$$

if all wires are twisted with equal angles.

In the case of solid strands such as 7, 19, 37, 61, etc., wires the results obtained from Formulæ [2], [3] and [4] are very close to actual figures. In the case of ropes, however, some other factors must also be considered.

In testing a full-size specimen of a wire rope there is always some nicking action between the strands as the load approaches a maximum, due to the compression of the hemp center. The larger the rope being tested or the stronger the rope of any diameter, the greater the compression of the hemp center will be. In fact, it has been found necessary in many cases where ropes are employed for very heavy duty such as in dredging operations on large sizes to manufacture wire rope with a wire

[1] Wire Rope Engineer, American Steel & Wire Company.

For presentation at the Annual Meeting, New York, December 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper, which contains many useful tables on rope stresses, may be obtained by members gratis upon application. All papers are subject to revision.

center consisting of a smaller wire rope contained inside of the larger one. Still another factor which will affect the general results is the kind of material of which the rope may be composed. Very high-strength material in rope construction reduces somewhat the efficiency of a wire rope when tested to rupture. By efficiency is meant the ratio between the break of the completed rope and the sum of the strengths of the separate individual wires.

No single value for efficiency of break can be assigned to any given construction such as 6 x 19 as this varies somewhat for the different grades of wire used in rope making and also the angle of lay of strands, etc., which may be changed from time to time to suit service conditions. This fact was recognized by the rope manufacturers of the country at their 1910 conference in the establishment of standard breaking strengths.

In making up specifications for wire rope for any purpose, the data on strength published by the various rope makers may be considered as fairly reliable. These values of breaking strengths are intended to represent approximately average values. They may vary two or three per cent under or they may run over. This variation, however, will make very little difference with the factor of safety used in the engineering calculations.

The stresses to which wire ropes are subject in service may be grouped in two main divisions, namely,

1 Direct stresses due to applied load
- Static tension
  - *a* Vertical lift
  - *b* Inclined lift
- Moving tension
  - *a* Acceleration of load
  - *b* Retardation of load

2 Indirect or induced stresses
- Bending
  - *a* Direct bending
  - *b* Reverse bending
- Horizontally suspended cable supporting load.

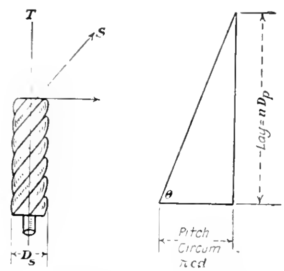

FIG. 1 EFFECT OF TWISTING WIRE ON THE STRENGTH OF ROPE

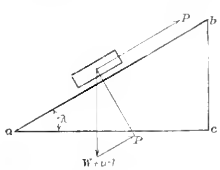

FIG. 2 DIAGRAM OF FORCES IN PULL ALONG INCLINED PLANE

STATIC TENSION

Considering these stresses separately, it is a simple matter to calculate the load to be lifted and add to this the weight of rope suspended vertically, thus obtaining the direct static tension.

Let W = load to be lifted
w = weight of rope per foot
l = length of rope suspended vertically
L = total load or tension.

Then

$$L = W + wl$$

INCLINES

For an inclined lift Formula [1] will be modified somewhat as follows (see Fig. 2):

Let λ = angle of incline
P = pull due to load $W + wl$
F = friction factor, which is a function of $(W + wl)$ and the angle of the incline λ.
$P = (W + wl)\ F \sin\lambda$.

The friction F of the cars on the incline operates normal to the line ab and is therefore a function of $\cos\lambda$. The maximum value is when $\cos\lambda = 1$, or on a level track, and the minimum for $\cos\lambda = 0$ when $\lambda = 90$ deg. Starting friction being the greatest, this alone need be considered. Assuming a value of 2 per cent,

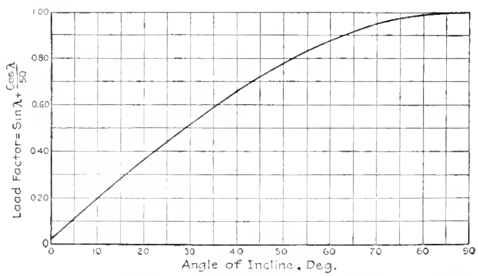

FIG. 3 VARIATIONS IN LOAD FACTOR WITH CHANGES IN ANGLE OF INCLINE

$$F = \frac{(W + wl)\cos\lambda}{50} \quad \ldots\ldots\ldots\ldots\ldots\ldots [7]$$

Therefore,

$$P = (W + wl)\left(\sin\lambda + \frac{\cos\lambda}{50}\right) \quad \ldots\ldots\ldots\ldots [8]$$

Values for the load factor $\left(\sin\lambda + \frac{\cos\lambda}{50}\right)$ for values of λ from 0 to 90 deg. are given in Fig. 3.

MOVING TENSION—ACCELERATION AND RETARDATION

In the case of very slow-moving ropes, the ropes stress in any straight portion will be equal to the load being lifted in the case of a vertical hoist or, on an incline, the tension due to the angle of incline, but there are many cases where rapidly moving ropes are subject to heavy stresses of acceleration or retardation where the factor of safety under static load is reduced very much by quick stops and starts. The value of the stress due to acceleration may be calculated thus:

Let T = time of acceleration
W = weight to be lifted, lb.
w = weight of rope per ft., lb.
E_r = modulus of elasticity of rope
a = acceleration or retardation of load, ft. per sec. per sec.
S = space in which acceleration or retardation is made
V = velocity of load, ft. per sec.
K = kinetic energy of the moving load
k = kinetic energy of the moving rope.

Then

$$K_t = K + k = C\ (W + wl) \quad \ldots\ldots\ldots\ldots [9]$$

where C is a constant by which the load is increased due to kinetic energy, and a factor representing the increase of the total load. Therefore,

$$K_t = \frac{WV^2 + wlV^2}{2g} = \frac{V^2}{2g}(W + wl) \quad \ldots\ldots\ldots [10]$$

but as

$$V^2 = 2aS$$

$$C\ (W + wl) = \frac{aS}{g}\ (W + wl) \text{ or } a = \frac{Cg}{S} \quad \ldots\ldots [11]$$

Also $\quad a^2t^2 = 2\ gC$

and if $t = 1$,

$$a = \sqrt{2gC} = 8.02\sqrt{C}$$

Indirect or Induced Stresses

Bending stress may be of two kinds, direct or reverse. As in the case of solid steel bars, reverse bending is much more severe than direct bending, resulting in greatly reduced life even if the size of sheaves used is fairly large.

Bending stress affects all ropes that are passed over sheaves, which service includes the vast majority of rope installations. Well-developed formulæ in mechanics give the value of this stress for solid round bars bent around a given diameter. When this problem has been considered in connection with wire rope more or less difficulty has appeared due partly to an erroneous conception of the fundamental principles which govern bending stress as applied to wire rope.

Several formulæ have been proposed to calculate the bending stress for wire rope. They all give values much larger than the actual values because the most vital and important factor of the entire problem has been neglected. Wire ropes are manufactured

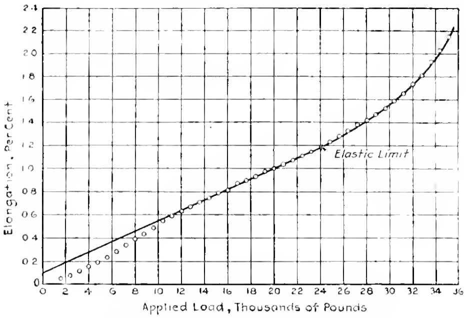

Fig. 4 Load-Elongation Curve of Wire Rope

not from *straight* wires but from *twisted* wires. The values obtained by these formulæ are correct, therefore, only for ropes composed of straight wires. That being the case, they are decidedly incorrect as applied to modern rope, which is made of *twisted* wires. When these formulæ were developed there were no experimental data available to check the results obtained, and they gained credence among engineers probably on account of the reputation of the authors who proposed them. In very similar manner the strength of ropes for many years was calculated as the aggregate strength of all the wires. Experimental data showed this conception to be wrong.

No check tests had been made to determine the modulus of elasticity of complete wire ropes. Owing to the twisting of wires to form wire ropes the modulus of elasticity of a wire rope is much less than that of a solid bar, as illustrated in Figs. 4 and 5, which represent curves of the modulus of elasticity of wire rope with hemp centers. Many other tests on similar ropes have proved conclusively that the modulus of elasticity of six-strand ropes will not run over 12,000,000 lb. and may be somewhat lower. In making such tests it must always be borne in mind that readings of elongation under light load are not as reliable—owing to the yielding nature of hemp core—as the values obtained under heavier loads. The values of the modulus of elasticity should be taken between the points where the stress-strain diagram is approximately a straight line.

Having determined the true value of the modulus of elasticity of a wire rope, we may now proceed to the determination of the bending stress in a wire rope. Considering the Reuleaux formula, $S = Ed/D$, if we replace E, the modulus of elasticity of a solid bar, with E_R, the modulus of elasticity of the rope as a whole, the formula becomes

$$S = E_R \frac{d}{D} \qquad [12]$$

which is the true bending-stress formula for a wire rope.

It should be specially noted that the value of S obtained is the stress per square inch of the greatest strained fiber, since it is the stress in the greatest strained fiber that determines the effect of the bending, just as it does in a beam under load. If we take the value of S and multiply it by the area of the wires in the rope, we obtain the actual bending stress in pounds. The interpretation of this value of the bending stress is important. The bending stress thus calculated shows the value equivalent to a direct tension on the rope.

Calculations may be made which show that over very small sheaves the bending stress by formula $S = E_R d/D$ gives a value greater than the strength per square inch of the material used in making wire rope. This shows that the elastic limit of the fibers of the steel has been exceeded and the rope has taken a permanent set.

The writer developed the formulæ given below for determining the modulus of elasticity of both strands and rope, which checks up with values obtained from a large number of experiments.

Considering first a strand, let E_s be the modulus of elasticity of a strand. Then E_s may be considered as a function of E, or

$$E_s = fE$$

Considering the first concentric strands composed of successive layers of strands, the modulus of elasticity may be determined by considering each layer of wires separately.

Let n = number of wires twisted together in one layer

nd = approximate circumference of pitch circle if the wires are laid straight (n should be in excess of 6)

d = diameter of individual wires composing the ring.

Then $\dfrac{\pi d}{\sin \alpha}$ = exact circumference of pitch circle (wires laid straight)

where α = angle subtended at the center of the ring by the radius of a single wire.

Also, let D_c = outside diameter of circular ring under consideration.

By trigonometry,

$$D_c = Cd$$

where C is an angular function depending upon the number of wires composing the circular ring.

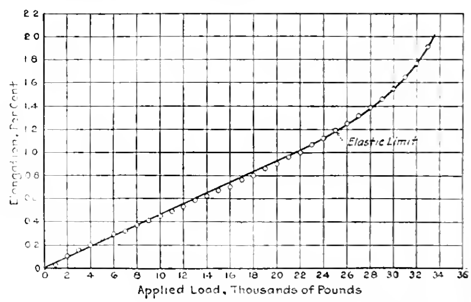

Fig. 5 Load-Elongation Curve of Wire Rope

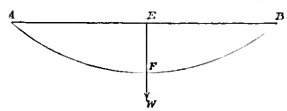

Fig. 6 Stresses in Horizontally Suspended Rope

$\dfrac{d}{\cos \theta}$ = the elongated diameter of the wires normal to the axis of the strand in the twisted arrangement.

where θ is the angle of wire relative to the axis of the strand, i.e., the developed angle of the helix formed by the twisted wire.

By trigonometry $\dfrac{\pi d}{\sin \alpha \cos \theta}$ = circumference of the pitch circle of the annular ring of twisted wires under consideration.

Let E_t = modulus of elasticity of the annular ring of twisted wires.

$E_t = fE$ and f is most nearly represented by the formula

$$f = \cos\theta\sqrt{\frac{D_e \sin\alpha\cos\theta}{\pi d}} = \cos\theta\sqrt{\frac{C\sin\alpha\cos\theta}{\pi}}$$

since $D_e = Cd$. Therefore

$$E_1 = E\cos\theta\sqrt{\frac{C\sin\alpha\cos\theta}{\pi}} \quad\ldots\ldots\ldots\ldots\ldots\ldots [13]$$

If $\theta = 0$, then $\alpha = 90$ deg. and $E_1 = E$.

Considering the quantity outside the radical, as θ grows smaller $\cos\theta$ approaches unity as a limit, hence

$$E\cos\theta = E \text{ at the limit } \theta = 0.$$

Considering the quantity under the radical with $\theta = 0$,

$$\frac{C\sin\alpha}{\pi} = 1 \text{ or } C = \pi$$

and Formula [13] may be written approximately as

$$E_1 = E\cos\theta\sqrt{\frac{D_e}{\pi d}}$$

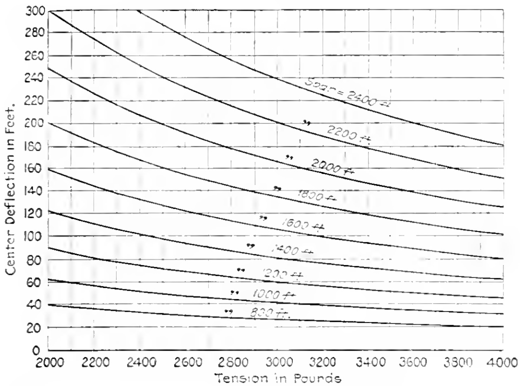

Fig. 7 Tension in Cable Spans for Distributed Load of 1 Lb. Per Ft.

Having determined the value of E_1 for one layer of wires, the value E_s for a strand of any number of layers or wires may be determined as follows:

Let E_1, E_2, E_3, etc., be the moduli of the various circular rings as determined by Formula [13], n_1, n_2, n_3, etc., the number of wires in the corresponding successive rings or layers, and E_s the modulus of elasticity of strand. The effect of various moduli upon the modulus of the strand as a whole will be determined by the number of wires and also by the modulus of the corresponding layer. Dividing this amount by the sum of the number of wires,

$$E_s = \frac{E_1 n_1 + E_2 n_2 + E_3 n_3 + \text{etc.}}{n_1 + n_2 + n_3 + \text{etc.}} \quad\ldots\ldots\ldots\ldots [14]$$

By means of this formula the values of the modulus of elasticity for any type of strand may be determined. If $E_1 = E_2 = E_3$, the modulus of elasticity of any strand $E_s = E_1$.

Considering a rope, the formula for modulus of elasticity takes the same form, only for E_1 we substitute E_s, using the following notation:

ϕ = angle of strands in the rope
N = number of strands in rope
d = diameter of strands

$\dfrac{\pi d}{\sin\beta}$ = exact circumference pitch circle

where

β = angle subtended at center of rope by radius of strand

$\dfrac{d}{\cos\phi}$ = elongated diameter of strand normal to axis of rope in the twisted arrangement

$\dfrac{\pi d}{\sin\beta\cos\phi}$ = exact circumference at pitch circle of strands of rope in the twisted arrangement

E_r = modulus of elasticity for rope

In a similar manner as before

$$E_r = E_s\cos\phi\sqrt{\frac{C\sin\beta\cos\phi}{\pi}} \quad\ldots\ldots\ldots [15]$$

For a compound rope of several layers of strands the modulus is determined as follows:

Let N_1, N_2, N_3, etc., represent the number of strands in successive layers, E_{r_1}, E_{r_2}, E_{r_3}, etc., the corresponding moduli and E_{mr} the mean modulus of rope. Then

$$E_{mr} = \frac{N_1E_{r_1} + N_2E_{r_2} + N_3E_{r_3} + \text{etc.}}{N_1 + N_2 + N_3 + \text{etc.}} \quad\ldots\ldots\ldots [16]$$

For a compound rope such as one of 6 ropes each having six 7-wire strands,

let Y = angle of rope strands in rope
ψ = angle subtended at center of rope by radius of rope strand
E_R = modulus of elasticity of compound rope

Then

$$E_R = E_r\cos Y\sqrt{\frac{C\sin\psi\cos Y}{\pi}} \quad\ldots\ldots\ldots\ldots\ldots\ldots [17]$$

Table 1 gives values of E_s and E_R, as obtained from Formulæ [14] and [15], and from the results of tests.

TABLE 1 MODULI OF ELASTICITY OF STRANDS AND ROPES

No. of Wires	Approx. Value θ for Outer Layer of Wires	Cos θ	Value of Modulus E_s by Formula	Average of Tests
7	9°–54′	0.9851	19,950,000	20,000,000
19	15°–30′	0.9636	17,760,000	18,000,000
37	16°–33′	0.9586	16,900,000	16,700,000
61	17°–8′	0.9556	16,600,000	17,000,000
Rope Construction	**Approx. Value of θ for Strand Angles**	**Cos θ**	**Value of Modulus E_R by Formula**	**Average of Tests**
6 × 7	14°–40′	0.9674	13,000,000	12,800,000
6 × 19	17°–52′	0.9518	11,400,000	11,400,000
8 × 19	20°–44′	0.9352	10,500,000	10,000,000
6 × 37	17°–52′	0.9518	10,800,000	10,400,000
6 × 42	19°–15′	0.9441	7,800,000	7,000,000

In obtaining the values of modulus of elasticity enumerated in Table 1, the value of E has been taken as 27,500,000 lb., since wire used in rope manufacture will not average much higher than 27,500,000. In fact, it may go as low as 25,500,000 and very rarely does it go as high as 29,000,000 lb. Soft bar steels on the contrary have a modulus of elasticity running about 29,000,000. Having determined the value of E_r for a given rope, the bending stress is readily obtained by use of the formula $S = E_r d/D$.

Reverse Bending

The value of reverse bending may be determined in exactly the same way as that of direct bending, but its effect is very deleterious, even if the amount is comparably small. If it were possible in the design of a machine not to have any reverse bends, the rope service would be much better; or, if a reverse bend is necessary, let it affect only one part of the rope, in which case the effect might be the same as that of simple bending.

There is one misconception in regard to bending which should be discussed at this point and that is, that it makes no difference whether a bend is 90 deg. or 180 deg. provided it goes around a sheave of a fixed diameter. The stress produced is the same in each case, and with the rope traveling between any two points all of the rope will have to take the bend whether it is 90 deg. or 180 deg. The only thing to be noted is that the bend is effective for a small fraction of a second longer in case it is 180 deg. as compared with 90 deg.

Stresses in a Horizontally Suspended Cable Supporting a Load

In this case a stress is produced in a rope suspended horizontally between two points due to the weight of the rope alone, and any load supported by the rope produces an additional stress which in most cases is not only equal to the load but to several times its value. In the case of a horizontally suspended rope, Fig. 6, assuming the curve to be parabolic in form, we may calculate stresses in a rope as follows:

Let L = total span in feet = AB
D = deflection in feet = EF
W = dead load at point F
w = weight per foot of the cable
S = tension in the cable at F
X = AE, position of load W with reference to point A.

Then, for the deflection due to weight of rope alone,

$$S_1 = \frac{wL^2}{8D} \text{ at the center of the span........[18]}$$

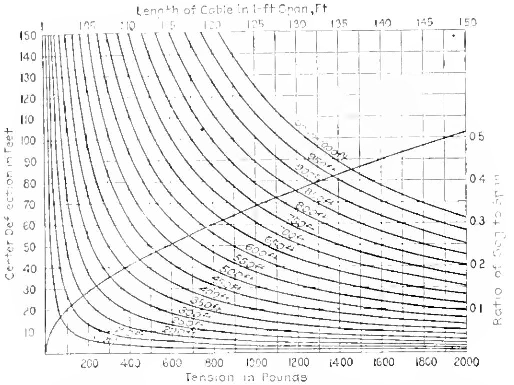

Fig. 8 Cable Tension in Terms of Center Deflection and Length of Cable for Different Ratios of Span and Sag

Formula [18] is applicable to all cases of uniformly distributed load such as a wire rope or large guy strand used for supporting a lead telephone or power cable, or a bare-copper high-tension feeder cable, at frequent intervals. The value of w must be taken, however, as the total weight per foot of both suspended and supported cable.

The stress due to the weight alone is

$$S_2 = \frac{WL}{4D} \text{ at the center of the span........[19]}$$

$$S = S_1 + S_2 = \frac{wL^2 + 2WL}{8D} = \frac{L(wL + 2W)}{8D} \text{....[20]}$$

From Formula [20] may be obtained the stress on any cable due to load and weight of cable.

The maximum stress on a cable span is at the supporting points A and B, Fig. 6, when the load is suspended in the center. Tension T at A or B equals tension in center plus the tension due to weight of rope wL and load W times the deflection D, or

$$T = \frac{S + D(wL + 2W)}{L} \text{..................[21]}$$

$$= S + D\left(w + \frac{2W}{L}\right) \text{............[22]}$$

Figs. 7 and 8 give the tension in cable spans in pounds for a distributed load of 1 lb. per ft. Fig. 8 also gives the length of cable in a 1-ft. span for different ratios of span and sag.

Preparation of Specification for Wire Rope

Close coöperation between the manufacturer and the engineer in drawing up a specification for wire rope will result in avoiding trouble which sometimes develops in a rope installation, or at least will improve rope service to the user. A few general remarks, therefore, in regard to specifications may not be out of place here.

Whenever possible, specify and use some standard construction of wire rope such as 6 x 7, 6 x 19, 8 x 19, 6 x 37, or 6 x 61. The relative flexibilities of these constructions are in proportion to the diameters of the wires from which they are made. Taking the value of the 6 x 7 rope as 100, the 6 x 19 will be 60; the 8 x 19, 50; the 6 x 37, 43; and the 6 x 61, 33. The sheave diameters will be in proportion to the values for these rope constructions.

Use the strengths shown in the manufacturer's rope catalog of some one of the four standard strengths of steel known by the following trade names:

a Crucible steel
b Extra strong crucible steel
c Plow steel
d Special brand improved plow steel (each maker has a trade name for this brand).

Physical properties of wire are sometimes specified, such as

a Tensile strength per square inch
b Elongation in 10 in.
c Bends over a fixed radius or proportionate radius
d Torsion test in 6- or 8-in. length.

Tensile Strength. Considering these in order, it is seen that, taking a rope of a given diameter and metallic sectional area and allowing for the loss of efficiency due to angle of lay of wires, it will have to have at least a certain strength per square inch in order to meet the required breaking strength.

Elongation. The elongation of rope wire is not very great as compared to annealed wire and the diameter of the wire is the determining factor. A fixed value for elongation covering all sizes of rope wire is unfair as well as untrue to actual conditions of steel manufacture.

Bends. Bends are sometimes specified on rope wire, the object being to eliminate any brittle wire, but no manufacturer would knowingly permit a single piece of brittle wire to be used in rope construction, as all wire would be tested when finished to eliminate brittleness. Rope wire will stand approximately six bends of 90 deg. alternately to right and left over a jaw with a radius equal to twice the diameter of the wire being bent.

Torsion Test. A torsion test in 6 or 8 in. is used by most wire manufacturers to test the uniformity of rope wire. Some rope specifications call for a test for torsion on wires to be used in rope. While it should not be necessary to specify this, still ungalvanized rope wire should stand in 8 in. as many twists as are obtained by dividing the constant 1.8 by the diameter of wire in inches, and proportionate twists in shorter lengths.

Factors Affecting Rope Service

One problem that is intimately linked up with rope service is the question of sheave diameter and the kind of bending to which a rope is subjected. Reverse bending should be avoided in every possible case as it has a very bad effect upon the durability of a wire rope.

For derricks the sheave diameter nowadays rarely exceeds 20 to 30 times the diameter of rope used, which is usually 6 x 19 or 8 x 19 construction. Hoisting machinery for coal towers, clamshell buckets for ore and coal handling are proportioned about forty times the rope diameter for 6 x 19 rope. Ladle cranes in steel mills use sheaves 30 times the rope diameter for 6 x 37 rope. Mine hoists use sheaves and drums from 60 to 100 diameters for 6 x 19 rope, and these are probably the most liberally proportioned of any machinery. Lift bridges have sheaves and drums 50 to 80 times the rope diameter for 6 x 19 rope.

One point that seems to have been lost sight of in designing machinery using large sizes of rope which require large diameters of sheaves and drums, is that in place of 6 x 19 rope it is possible to use 8 x 19, 6 x 37 or 6 x 61 rope and reduce the diameter of both sheaves and drums to more reasonable proportions, and still not have any greater bending stress in the rope. Crane builders have for years been using the 6 x 37 rope with good success and the writer would recommend for general hoisting work (excepting mines) that for ropes larger than 1½ in., 6 x 37 rope be used, and for those larger than 2 in. that 6 x 61 rope be employed.

Another factor affecting rope service is the personal equation of the operator who is to handle the wire rope. The skill with which any rope is handled coupled with freedom from sudden jerks or quick stops vitally affects its life. Similarly, the external wear or abrasion of the wires composing the rope influences the durability of the rope. Properly aligned sheaves, loads that are not excessive, and absence of any points where friction would cause undue wear, will all contribute to longevity of rope service. If the external wear is excessive, the rope maker can only partially overcome this difficulty by the use of stronger and harder grades of steel. Of the four grades of steel mentioned above, crucible is the softest and improved plow steel the hardest.

It might be thought at the first glance that all it is necessary to do to solve the problem of abrasion is to use the hardest possible steel. This is not necessarily true, because each of the four grades has physical characteristics that are possessed by the others, only in a greater or lesser degree. If, therefore, in the design of a machine requiring wire rope it is found that crucible steel will give an ample factor of safety and sheaves and drums are of suitable size so that this grade of rope may be readily supplied, then the chances are that crucible steel will be the best grade of rope to be used, bearing in mind always the question of abrasion. Such is the case in the vast majority of mining operations in the United States. Some mining operations are, of course, using plow steel, but the bulk of the coal-mining industries use crucible-steel rope, or at the most the extra strong crucible, with here and there an occasional plow-steel rope. In other metal mines both crucible- and plow-steel ropes are being employed. In some cases where loads have been increased the grade of rope employed has been changed from crucible or plow steel in order to take care of the increase in load. Iron-ore mines, for instance, are generally using the plow-steel grade of rope because of the heavy loads lifted and the grinding action of the iron-ore dust which becomes more or less intimately attached to the rope in the process of hoisting.

Corrosion is another element which affects the service factor. This is due to the rope's being subjected to the action of the elements or an acid mine water, sulphurous gases, etc. The higher the grade of steel, the more rapid will be the corrosion resulting from such exposure. Good lubrication where it is possible to maintain it will have a large influence in counteracting the corrosive effect, but in some cases it is next to impossible to get any lubricant to stay on the rope, and in such cases only the resistant action of the steel itself to the corrosive effect is left. When this corrosion has reached the point where pitting has reduced the metallic sectional area of the wires and they have started to break, then the life of the rope is practically gone.

Ascertaining the proper value of all stresses, together with the choice of a reasonable and safe factor of safety, will contribute largely to the longevity of wire rope under any set of conditions.

THE COOLING LOSSES IN INTERNAL-COMBUSTION ENGINES AS AFFECTING THEIR DESIGN

By C. A. NORMAN,[1] COLUMBUS, OHIO

THERE is considerable evidence that a great part of the heat loss to jacket water in an explosion engine occurs, not during the expansion stroke, but rather in the exhaust passages. Coker found by direct measurement a temperature drop of 150 deg. cent. (270 deg. fahr.) between the gas in the cylinder at the end of the expansion stroke and the gas in the exhaust pipe. Dugald Clerk found indirectly that of a total measured jacket loss of 25.4 per cent, about 16 occurred in the cylinder, and consequently 9.4 per cent in the exhaust passage. Losses in the exhaust passages, however, have no influence on the thermal efficiency of the engine. In order to arrive at the influence of varying proportions and speeds on the efficiency it would be necessary to determine separately the losses during the expansion stroke for a whole series of engines, varying only one factor at a time. No such investigation has to the knowledge of the writer been undertaken.

The formula for cooling loss developed later by the author from the published work of Clerk and others, while based on purely theoretical considerations, has nevertheless been found to represent fairly both the results of careful experiments and general experience, and its presentation at this time would therefore seem to be abundantly justified.

Method Employed by Dugald Clerk in His Experiments

Clerk equipped an ordinary gas engine with a contrivance enabling him momentarily to close the inlet and exhaust valves while the engine continued to run. A series of recompressions and reëxpansions of the same burned charge took place in the cylinder. A sample diagram of these fluctuations is given in Fig. 1.

With no cooling and no friction losses the recompression ought always to carry the gas temperature back to its value at the beginning of the previous expansion. As a matter of fact, Fig. 1 shows a constant falling of the temperature from point B to points D, F, H, etc. By means of calculation or determination of the temperature at one point, definite temperature values can be assigned to all the other maximum- and minimum-pressure points on the diagram and an estimate of the actual temperature drops and the average temperatures during the strokes can be made. With the aid of the speed of the engine it is also possible to give the results in terms of reduced temperature drops per second corresponding to certain average temperatures. The results are given in the form of the curves reproduced from Clerk's work in Fig. 2.

These curves show reduced temperature drop per second on the cold engine running light at 120 r.p.m. for a full expansion stroke (a) and for the upper 3/10 expansion stroke (a'). Also for the hot engine running light at 160 r.p.m. for the full expansion stroke (b) and loaded during the upper 3/10 expansion stroke (b'). The intersection of the curves with the temperature axis gives the mean temperature of the wall.

The curves in Fig. 2 give temperature drop, not heat loss. The expansion work in an engine cylinder is directly connected with the temperature by means of the specific heat. On the other hand, the work can be directly evaluated from the indicator diagram. In this way the specific heat of the gas in the cylinder at various temperatures can be ascertained.[1] Clerk gives the values found in Table 1.

Table 1 gives a striking illustration of the increase of the specific heat with the temperature. This increase is not uniform, however. It is considerable at lower temperatures, but almost nil at higher temperatures. Clerk in his original paper deems this behavior partly due to delayed combustion and hence considers his specific-heat values as merely "apparent."

Very thorough investigations of the specific heats of gases have been carried out by Nernst and his pupils.[2] From these it would appear that only carbon dioxide with certainty behaves in the manner indicated by Clerk's experiments. The specific heat of all other common gases, even that of superheated steam of sufficiently

[1] Professor of Machine Design, Ohio State University.

[1] See Proceedings of the Royal Society, A, vol. 77, p. 499.

[2] See Nernst, Theoretische Chemie, 1913, p. 267.

high temperature, shows rather a linear increase with the temperature. For the mixture used by Clerk the specific-heat values he gives seem to be too high, at least at lower temperatures. This is the opinion also of the Gaseous Explosion Committee of the British Association. Yet, as will be seen below, the deviations are not very great, considering the accuracy possible. By means of his heat values Clerk has succeeded in accounting very satisfactorily and in a new and striking manner for the heat balances in several combustion engines. In the illustrative examples figured in this paper these values have at times been used. This can be done without question when only general laws for design are to be established.

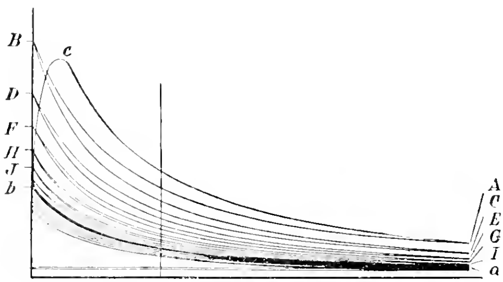

FIG. 1 CLERK DIAGRAM OF EXPLOSION AND ALTERNATE COMPRESSION AND EXPANSION OF HOT GASES IN ENGINE CYLINDER

Clerk gives the average composition of his combustion gas as follows:

	Volumes
Steam (assumed gaseous)	11.9
Carbon dioxide	5.2
Oxygen	7.9
Nitrogen	75.0
	100.0

The molecular weight of this mixture would be 27.96, or practically that of pure nitrogen, and the weight of 1 cu. ft. at 0 deg. cent. and 760 mm., 0.078 lb. The specific heat for the mixture at various temperatures is given in Table 2, in customary units, the values having been derived from the Clerk and the Nernst values.

The difference between the two series of specific-heat values given in Table 2 amounts to about 10 per cent in the middle of the range, but is barely 1 per cent at atmospheric temperature and less than 2.5 per cent at 1500 deg. cent. (2700 deg. fahr.). With the aid of Clerk's specific heats the cooling curves in Fig. 3 have been obtained. These curves give the cooling loss during the whole expansion stroke, reduced, however, to heat units per unit weight of gas per second. If, then, we compute the work theoretically obtainable from 1 lb. of gas with the temperatures and the expansion occurring, and if we compute the heat necessary to raise 1 lb. of gas from the temperature at the end of compression to the temperature at the end of the explosion, we can derive the actual expansion work as well as the percentage cooling loss. This, however, applies only to the Clerk engine.

APPLICATION OF CLERK'S HEAT-DROP CURVES TO OTHER ENGINES

Influence of Surface-to-Volume Ratio.—Clerk's experimental engine had the following dimensions:

Cylinder diameter, in.	14
Stroke, in.	22

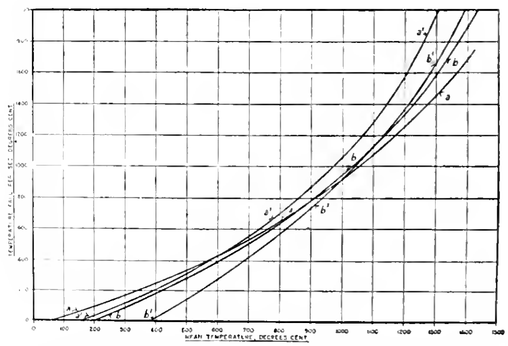

FIG. 2 TEMPERATURE DROP INCURRED PER SECOND AT DIFFERENT MEAN TEMPERATURES CALCULATED IN TIME. EACH LINE IS THE MEAN OF THREE CARDS UNDER THE GIVEN CONDITIONS

120 r.p.m. Cold { (a) Whole stroke; (a') Upper 1/10 stroke 160 r.p.m. Hot Load 50 b.h.p. { (b) Whole stroke; (b') Upper 3/10 stroke

Total cylinder volume with full-out piston, cu. ft.	2.41
Total cooling surface with full-out piston, sq. ft.	11.2
Sq. ft. of cooling surface per cu. ft. of volume	4.64

Now, the most simple assumption to make with regard to cooling losses is that they vary directly as the ratio of surface to included volume. For this assumption there is considerable support in the results of experiments with explosions in closed vessels. Table 3 gives data on the surface and capacity of the vessels used by several different experimenters, and Table 4, values of the temperature drop in the same vessels as recorded by Clerk.

The values in Table 4 have been plotted in Fig. 4. The experiments were carried out at widely differing places and times by

TABLE 3 EXPLOSION EXPERIMENTS WITH CLOSED VESSELS

Reference No.	Experimenter	Capacity of vessel, cu. ft.	Internal surface of vessel sq. ft.	Ratio of surface to volume, sq. ft. per cu. ft.
1	Hopkinson (large vessel)........	6.2	17.3	2.79
2	Bairstow and Alexander Hopkinson (small vessel)........	0.82	5.02	6.12
3	Hopkinson (small vessel)...	0.684	4.33	6.33
4	Clerk (first vessel)........	0.183	1.79	9.78
5	Massachusetts Institute Technology	0.180	1.79	9.94
6	Clerk (second vessel)..	0.150	1.60	10.65

different experimenters, using different methods, with vessels of differing shapes. It should not cause any surprise that the points are scattered. Nevertheless, it can hardly be denied that they are more naturally represented by straight lines, as shown, than in any other manner.

As far as experimental evidence goes, it then certainly seems to counsel the assumption of direct proportionality between heat loss per unit time and the ratio of surface to included volume. For geometrically similar vessels this ratio varies inversely as the linear dimensions. For similar engines running at the same number of revolutions the cooling losses would then vary inversely as the cylinder diameter. This has led to the conclusion that the cooling losses could be reduced almost to zero by employing sufficiently large dimensions. How unjustified this is will appear after some further scrutiny.

Influence of Speed. In the derivation of the heat-loss curve from Clerk's experiments it has been tacitly assumed that the heat loss varies directly as the time. No other assumption with regard to heat transfer has ever been made. With all other conditions equal, the heat loss in an engine should then vary inversely as the r.p.m. It is important, however, to note that all other conditions should be equal. It is known that if an engine is speeded up, something may be gained in efficiency, yet not as much as should be expected if the heat loss dropped in direct proportion to the increase in speed. The reason for this is often given as increased turbulence with increased speed. This would, of course, increase the convection losses. If the valves are correctly located and correctly proportioned there should be no more turbulence at high speed than at low speed, unless the turbulence is intentionally increased in order to accelerate combustion.

For the same engine, an increase in r.p.m. means an increase in piston speed and an equal increase in gas velocity along the walls. The old idea was that the coefficient of heat transfer from gases increased directly as the square root of the rubbing velocity of the gas. We can probably do no better in the present connection than adhere to this old idea, even though it expresses the relations somewhat too simply. We should then put the heat loss directly proportional to the square root of the piston speed. Consequently, if the known heat loss of a certain engine be denoted by L_o, and its surface-to-volume ratio and its piston speed, and r.p.m. by R_o, V_o and N_o, respectively, then for another similar engine with values R, V and N, working under the same temperature conditions the heat loss

$$L = L_o \times \frac{R}{R_o} \times \frac{N_o}{N} \times \sqrt{\frac{V}{V_o}} \qquad [1]$$

In the form just given the formula is serviceable only for comparing with each other engines working under similar temperature conditions, with similar fuels. It does not take into account variations in expansion ratio, or in maximum temperature; nor does it give absolute heat losses in heat units per unit weight of gas. It can easily be given this added range of usefulness by connecting it with the heat losses per second per unit weight of gas given for varying mean temperatures for the Clerk engine by the curve in Fig. 3.

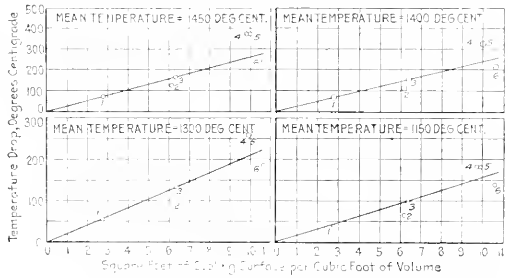

Fig. 4 Explosion Experiments with Closed Vessels: Drop in Temperature in 0.05 Sec. at Mean Temperatures Given. Pressure before Explosion, Atmospheric

6	10.65	238	216	184	138

it is possible then to estimate from the expansion ratio of the engine the temperature drop during the expansion by the use of an assumed polytropic exponent. From this we get close enough for our purpose the mean temperature during expansion as an arithmetic average. The corresponding heat loss C is read from the curve in Fig. 3 and it is the loss in B.t.u. per lb., or cal. per kg. of gas used for an expansion stroke lasting one second. To get the loss for any other duration of stroke it is simply necessary to multiply C by the actual duration in service. If the actual r.p.m. is N, this duration is $30/N$. The surface-to-volume ratio in the Clerk engine was 4.64 sq. ft. per cu. ft., and the piston speed at 160 r.p.m.—the speed at which the curve ap-

plies—586 ft. per min. Consequently, for any engine of surface-to-volume ratio R and piston speed V the expansion cooling loss in heat units per unit weight of gas used is

$$L = C \times \frac{30}{N} \times \frac{R}{4.61} \sqrt{\frac{V}{586}}$$

or

$$L = 0.267(CR/N)\sqrt{V} \ldots\ldots\ldots\ldots [2]$$

In Formula [2] R is expressed in sq. ft. per cu. ft., V in ft. per min., and N in r.p.m., while C can be either in B.t.u. per lb., or cal. per kg., or in any other units for which a C curve is available. If R should be given in sq. in. per cu. in., which is more convenient in most cases, then

$$L = 3.2(CR/N)\sqrt{V} \ldots\ldots\ldots\ldots [3]$$

where V is the piston speed in ft. per min. as is customary.

Application of the Cooling-Loss Formula to Actual Cases

Influence of Absolute Dimensions on Cooling Losses. Assume in the first instance that the piston speed does not vary. Particulars of series of such engines for a piston speed of 1000 ft. per min. and a bore-to-stroke ratio of 1:1.5 are given in Table 5.

TABLE 5 ENGINES WITH PISTON SPEED OF 1000 FT. PER MIN. AND STROKE-TO-BORE RATIO OF 1.5

Diameter, in.	3	10	15	30	42
Stroke, in.	4.5	15	22.5	45	63
R.p.m.	1333	400	266	133.3	95

In this case the r.p.m. varies inversely as the diameter, and so does the surface ratio. Consequently for the same C, L is constant. Thus, as far as the formula for the same expansion ratio and the same maximum temperature goes, the cooling losses and hence the indicated efficiency of these engines would be the same for all dimensions. Actually in order to avoid cracking of the metal, the cooling will have to be much more efficient for the larger engines. If they are double-acting, then even the pistons will be water-cooled. Even so, the maximum temperatures and maximum pressures will have to be kept down. The larger engines will therefore have a tendency to be rather less efficient than the smaller ones. On the other hand, with very high values of N the combustion is likely to consume a large part, if not the whole, of the stroke. In many cases, in fact, a good deal of the combustion will take place in the exhaust pipe. This can be prevented by extremely efficient carburization and ignition. Yet, on the whole, the likelihood is that, with the same compression, the best efficiencies will be found in the middle of the range. This would seem to be borne out by experience.

It may, however, be said that unvarying piston speed for all dimensions does not correspond to actual conditions. In some aeroplane and automobile engines piston speeds are found approaching, if not exceeding, 2000 ft., while it might perhaps be conservative to let the piston speed of very large engines remain below 750 ft. Suppose that at the large-size end the piston speed is half of what it is at the small-size end. The number of revolutions at the large-size end would be only half of what it would have to be to limit the cooling loss to its value at the small size end, piston speeds being equal. This would tend to make the cooling loss twice as large at the large-size end. On account of the lower value of the piston speed this loss is reduced in the ratio of $\sqrt{2}$. The upshot is that the loss would be about 40 per cent greater for the large size.

There is then absolutely no reason to look for high efficiency in large dimensions. High speed, even though connected with high piston speeds, is preferable, even from the pure efficiency point of view—provided the combustion can be effected satisfactorily.

Influence of Varying Stroke-to Bore Ratio. In this paragraph it will be assumed that the change in stroke-to-bore ratio is not consequent upon a change in expansion ratio. The question is: With a given expansion ratio and temperature range, how should a cylinder be proportioned for best efficiency? A basic cylinder of 5 in. diameter and 6 in. stroke, with the same total volume and the same clearance volume for all other proportions, will be considered. The expansion ratio may be 5—that of the Clerk engine; the speed, 1200 r.p.m.; the piston speed will vary from case to case.

Using Formula [1] the conditions found are those recorded in Table 6.

TABLE 6 ENGINES WITH UNVARYING VOLUME AND VARYING STROKE-TO-BORE RATIO

Ratio, stroke to bore	1.0	1.2	1.4	1.6	1.8	2.0	2.5
Diameter, in.	5.3	5.0	4.74	4.53	4.35	4.2	3.9
Stroke, in.	5.3	6.0	6.63	7.25	7.81	8.4	9.75
R, sq. ft. per cu. ft.	12.7	12.8	13.1	13.3	13.5	13.8	14.3
Piston speed, ft. per min.	1060	1200	1326	1450	1562	1680	1950
Cooling loss, per cent (for Clerk engine 16 per cent).	7.85	8.4	9.05	9.6	10.1	10.8	12.0

The cooling loss increases regularly with increasing stroke-to-bore ratio. The absolute magnitude of the loss is small and the extreme variation changes the thermal efficiency by only 4 per cent. However, this 4 per cent means from 15 to 20 per cent saving in fuel. In an aeroplane 1 lb. of weight would be saved in fuel for a 10-hr. flight for every hp. of the engine output. This is not negligible, and will count more and more as longer and longer flights over sea, or over enemy territory, are attempted.

Influence of Varying Stroke-to-Bore Ratio Consequent on Varying Expansion Ratio. The next step is to investigate the influence of varying expansion ratio on engines of the same output and the same speed, the increase in expansion being brought about by lengthening the stroke. With increased compression and increased stroke the output per sq. in. of piston area will increase for the same number of revolutions. To obtain equal output the cylinder diameter will have to decrease with increased expansion ratio, as indicated in Table 7.

TABLE 7 INFLUENCE OF VARYING EXPANSION RATIO ON ENGINES OF THE SAME OUTPUT AND THE SAME SPEED

Volumetric expansion ratio	3	5	7	9
Cylinder diameter, in.	5	4	3.5	3
Stroke, in.	5	6	7	7.5

Indicated work, approx., cal. per kg. of gas	95	132	151	165

Polytropic exponent in computation of temperature drops, 1.3; compression work assumed equal to 30 per cent of expansion work.

As Table 7 shows, while the cooling loss increases 18 per cent, the indicated work increases 74 per cent. The value of high expansion, even though gained by increased stroke-to-bore ratio and decreased cylinder diameters, is hereby clearly demonstrated. For average conditions, however, a high-expansion engine would be more efficient with a large diameter and a short stroke than with a small diameter and a long stroke.

Character of the Combustion in High-Speed Engines. In Table 7 the cooling losses and the indicated work are given in heat units per unit weight of gas. If to obtain percentages an attempt were made to calculate the thermal efficiency of the engine by reference to the heat supplied during combustion, some very astonishing figures would result, such as those in Table 8. Here the maximum temperature has been assumed equal to 3270 deg. fahr. (1800 deg. cent.), in all cases and the mechanical efficiency equal to 0.85.

TABLE 8 APPARENT SHAFT EFFICIENCIES FOR ENGINES IN TABLE 7

Shaft thermal efficiency from indicated work in Table 7 (mech. eff. 0.85)	0.236	0.35	0.42	0.48

It is evident that, even though 7 and 9 may be unusual expansion ratios in actual engines, we can never hope to attain brake efficiencies as high as those in Table 8. In arriving at these efficiencies no use has been made of the calculated cooling losses; we have simply taken a polytropic-expansion exponent equal to 1.3 and assumed that all heat is added before the expansion commences to take place.

Clerk in his paper before the Royal Society concludes from his experiments on an engine running at only 160 r.p.m. that some combustion is proceeding even during his first reëxpansion, i.e., after the whole normal expansion stroke and a whole intervening compression stroke. All experiments with closed vessels show gaseous explosions to take certainly not less than $\frac{1}{40}$ sec., and this only with over-rich mixtures. With normal mixtures, it takes a much longer time than that to reach the maximum pressure. Turbulence accelerates combustion very much. Yet such direct experiments as we have seem to show that with normal mixtures even a turbulent combustion would take all of $\frac{1}{40}$ sec. One-fortieth of a second, however, is exactly the time occupied by the whole expansion stroke of an engine running at 1200 r.p.m. We have then absolutely no reason to assume that the combustion is complete before the expansion commences. In the series of engines just considered, it is far more reasonable to assume that it continues during the whole expansion stroke.

Assuming this we might approach the conditions actually obtaining by figuring with an isothermal expansion. During such an expansion all the heat added passes directly into work. Assume a temperature of 1600 deg. cent. (2912 deg. fahr.) to obtain during the expansion, then with an expansion ratio of 5 we find for the corresponding engine in Table 7 the values given in Table 9.

TABLE 9 SHAFT EFFICIENCY AND COOLING LOSS OF ENGINE OF TABLE 7 WITH EXPANSION RATIO OF 5, ASSUMING ISOTHERMAL EXPANSION

	B.t.u. per lb.	Cal. per kg.
Isothermal expansion work (gas constant = 0.071)..	385	214
Heat added between compression temperature (708 deg. fahr., 375 deg. cent.), and max. temp. (C_v = 0.225)	496	276
Cooling loss, estimated	162	90
Total heat supplied.	1043	5803
Compression work (exponent = 1.3)	104	58
Indicated work	281	156
Shaft efficiency (mech. eff. = 0.85).	0.229	0.225
Cooling loss, per cent	15.5	15.5

The shaft efficiency is now about what would be expected from an engine of this size and speed, and the cooling loss is considerably increased. The main reason for the lowered efficiency, however, is not cooling loss, but delayed combustion. To increase efficiency in explosion engines running at very high speeds, the main prerequisites are extremely efficient carburation, extremely efficient ignition, and *perhaps*, if feasible, some means for increasing the turbulence during combustion. It would hardly be good practice to increase turbulence by means of greater gas velocities and greater throttling losses in valves.

DAYLIGHT VS. SUNLIGHT IN SAWTOOTH-ROOF CONSTRUCTION

By W. S. BROWN, PROVIDENCE, R. I.

Many processes of manufacturing require for best results, natural illumination consisting of sufficient and well-diffused daylight with, at the same time, however, the important limitation that little or no direct sunlight shall fall upon the working plane. That is, there is a sharp distinction between daylight and sunlight and their relative desirability. The former consists of illumination by reflected and refracted light, properly designed fenestration, resulting in an evenly distributed, well-diffused light with consequent lack of sharp shadows and contrasts. The latter, or illumination by direct sunlight, is objectionable for many reasons of varying relative importance, such as the following: Its heating effect, especially in warm, southern climates; its color which has a sensation value containing a greater proportion of red rays than daylight; its actinic effect upon materials used in the manufacturing processes; and the fact that it is unidirectional and of excessive intensity resulting in glare, sharp shadows and contrasts.

Diffusion of daylight in sawtooth buildings is obtained by placing the sawteeth so that the glass or lighting area faces the northern sky; sufficient intensity being dependent, among other things, upon the size and slope of the lighting area. Evenness of distribution is procured by properly apportioning the lighting areas. The amount of direct sunlight admitted daily, the time of its admission, and its duration are evidently dependent upon three considerations, the last two of which may be varied within certain practical limits. They are:

a Day of the year, determining as it does the sun's path across the sky

b Direction in which the lighting area faces as regards the points of the compass

c Slope of the lighting area.

For a given lighting area, a variation in its slope is accompanied by a very appreciable change in the amount of daylight admitted. That is, as the pitch of the lighting area is made steeper, the amount and duration of direct sunlight entering the building is lessened, but only at the expense of the general illumination. Conversely, as the slope of the lighting area is decreased, the intensity of daylight is correspondingly increased, but there also is concurrent therewith a greater amount and duration of direct sunlight. The question then becomes: How steep should this slope be? What is the proper balance between the two contending requirements of little sunlight and much daylight? Also at what time of day will direct solar rays fall upon the working plane, in what locations and volume, and for how long a period?

Naturally, no general answer can be given, but each individual problem should be worked out only after careful study has been made of the particular conditions and requirements which have to be met, not excluding first cost. In the Southern States, for example, the tendency is to adopt a more nearly vertical lighting area than in the northern part of the United States or Canada, on account of the greater altitude of the sun and its intense heat. Occasionally it has been found advantageous to so locate machinery as to avoid any direct sunlight during the working hours.

[1] Industrial Engineer, F. P. Sheldon & Son. Assoc-Mem.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

With a view, therefore, to clearing up such questions as these, the writer's firm, F. P. Sheldon & Son, undertook to work out, in connection with what empirical data they already had, a rational method of design for sawtooth-roof construction.

The subject is necessarily divided into two closely related parts, the first concerning *direct sunlight*, its amount, time of admission, duration, and location on the working plane; the second relating to intensity of *daylight* upon the working plane.

Part I Orientation of Sawtooth Buildings and Slope of the Lighting Area as Related to Requirements of Least Direct Sunlight

In the practical problem of the sawtooth roof, the effective slope or *vertical angle* of the lighting area, on account of projecting jets, gutters, and sash rails, and the interference of roof rafters, etc., is *greater* than the pitch of the glass itself; this often amounts to as much as 7 or 10 deg. Similarly the *horizontal angle* or bearing of the lighting area with respect to the sun's rays may be greater or less than the nominal angle on account of projecting vertical sash bars, etc. This difference often amounts to as much as 5 or 8 deg.

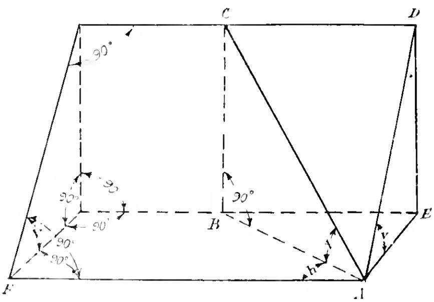

Fig. 1 Path of Direct Sunlight

The position of the sun at any given time depends upon the latitude of the place, time of day, and calendar date, and may be obtained from standard altitude and azimuth tables. Knowing these, the time of admission and duration of direct sunlight for any day of the year may be calculated as follows:

In Fig. 1, let the plane determined by the three points, A, C and D represent the lighting-area plane, and let points A, B and E define a plane parallel with the horizon. These two planes intersect in line AF. The acute angle v is then the effective slope or vertical angle of the lighting-area plane.

Also let line AB represent the horizontal direction or bearing of the sun with respect to the building at any assumed calendar date and time. That is, angle h is the difference between the sun's true bearing or azimuth and the true corrected bearing or azimuth of the lighting-area ridges, each azimuth being read easterly or westerly from north, according to whether morning or afternoon conditions are being computed.

Now pass plane ABC through AB perpendicular to plane ABE cutting the lighting-area plane ACD in line CD. By construction this plane also contains the sun's altitude line through point A. Consequently, it is evident that if vertical angle x is greater than the altitude of the sun, a condition of total shade exists within the building at the given time. And contrarywise, if x is less than the solar altitude, the sun is in front of the plane of the lighting area and some direct sunlight is entering the building.

Now, to find x in terms of v and h (see Fig. 1),

$$AE = ED \cot v$$

and

$$AB = ED \cot x$$

and

$$\cos (90 - h) = \frac{AE}{AB}.$$

Substituting in the last equation the values of AE and AB,

$$\cos (90 - h) = \frac{\cot v}{\cot x}$$

whence,

$$\sin h = \frac{\cot v}{\cot x}$$

and

$$\tan x = \sin h \tan v \quad [1]$$

From the above equation exact information may be obtained as to the time of admission of direct sunlight and the number of hours of its duration. The solution of a numerical example will illustrate the method of procedure.

A Numerical Example, Sunlight Conditions

Given a sawtooth building located in north latitude 36 deg. Orientation of building is such that azimuth of sawtooth ridges = 99° 08′ E. Angle of glass = 73°. *Required* to find sunlight conditions on June 10 (sun's declination 23° N.).

By inspection, according to azimuth tables, sunlight will enter the building from sunrise until at least 9:20 a. m. apparent time, because the sun's azimuth up to that time is less than that of the sawtooth ridges. The method now consists in finding by trial at what time the sunlight entirely disappears from the building.

Assume 10:20 a. m., at which apparent time, according to the tables, the sun's azimuth = 114° 08′ E., and its altitude 64° 46′. Now, v = 73° plus a correction for projecting jets, gutters, etc., as previously explained. (This may be found from detailed section of building and in this case will be assumed as 7°.) Then $v = 73° + 7° = 80°$). Applying the correction as explained above,

$$h = 114° \, 08' - (90° \, 08' - 5°) = 20°.$$

Entering Equation [1],

$$\tan x = \sin 20° \tan 80°$$

whence

$$x = 62° \, 43'.$$

Since at this time the solar altitude (64° 46′) is greater than x, a small angle of sunlight is entering the building. The above process may be repeated with a slightly greater assumed value of h, with the result that within a few minutes all direct sunlight will be found to be entirely excluded from the building.

To obtain afternoon conditions, the operation should be further continued until such time as sunlight is found to reënter as follows:

In this case, instead of assuming the time, and computing h, the reverse method will be pursued and, as a further short cut, it may be reasoned that since the lighting area faces slightly toward the east (that is, N, 9° 8′ E.), h at the transition period will be less than in the morning.

The westerly azimuth of the sawtooth ridges is now used for reference with the tables and equals 90° 0′ — 9° 8′ = 80° 52′. Try $h = 6°$, at which time the sun's azimuth becomes (80° 52′ — 5°) + 6° = 81° 52′, the apparent time being, from the tables 4:34 p. m., and the sun's altitude being from the tables 30° 10′. Entering Equation [1],

$$\tan x = \sin 6° \tan 80°$$

whence

$$x = 30° \, 41'.$$

Since x is 0° 31′ greater than the solar altitude, it is evident that no direct sunlight is entering. However, the angular difference is very slight, and if the computations were carried on a step further, sunlight would be found to come in approximately five minutes later.

In this case, then, on June 10 a condition of total shade exists within the building from approximately 9:20 a. m. until 4:34 p. m., *apparent time*. Where the apparent time is different from standard time, the proper allowance should, of course, be made. Furthermore, an additional correction must be applied in places where the daylight-saving plan is in effect.

Generally it will be found advisable to solve a given problem for at least two sets of conditions, that of the longest day of the year (June 21, declination, 23½° N.) and the average day of the year (March 21 and September 23, declination, 0°).

In the example above, it will be noted that the duration of total afternoon shade is 4 hr. and 34 min. and is considerably greater than the duration of morning shade, which is only 2 hr. and 40

min. This is due to facing the lighting area slightly (9° 8′) toward the east, and suggests quite a range of possibilities as regards orientation.

By applying the principles of descriptive geometry, the amount and location of direct sunlight at any given time may be obtained, if desired, by finding the lines in which the solar rays through the top and bottom limits of the lighting area intersect the working plane—the direction of these rays being taken from altitude and azimuth tables. It may also in this case be necessary to include the effect of side walls, division walls, etc.

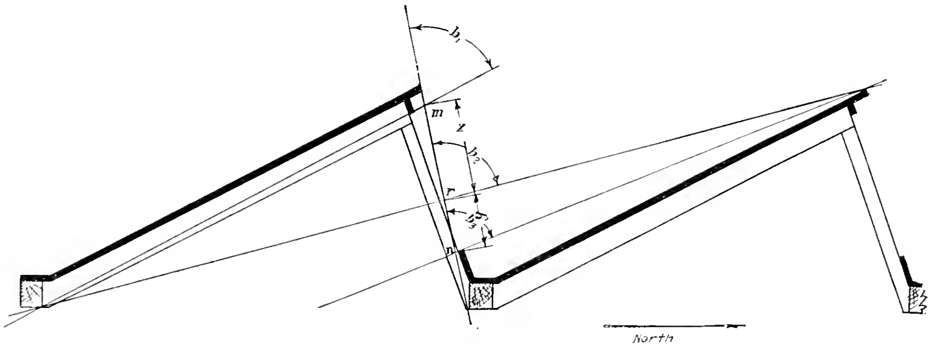

Fig. 2 Area of Direct Skylight Admission

For convenience, Table 1 is appended, giving different values of x for assumed values of h as applied in the second method of the example given above. Its use makes unnecessary any reference to trigonometrical tables, unless closer results are desired, for angles not given.

Part 2 The Relative Intensity of Daylight Received from the Northern Sky as Influenced by the Size and Slope of the Sawtooth Lighting Area

It doubtless has been noted that, by essence, Part 1 lends itself to exact mathematical solution. This is not the case, however, with Part 2, for which, as will be explained later, the answer is not to be found so precisely on account of the necessity of introducing certain more or less arbitrary and variable factors. It should, therefore, be applied only with discrimination and strict regard for its practical limitations.

The total amount of diffused daylight entering a building through sawtooth sash and made available for use (direct sunlight being excluded) may be analyzed as consisting of:

d = light from sky *directly* incident upon the working plane

rd = light from sky *directly* incident upon the underside or ceiling of sawtooth roof and thence being diffusely *reflected* to room below (one reflection)

r_1c = *combined* light from *sun and sky*, diffusely reflected from upper outdoor surface of adjacent sawtooth roof directly to room below (*one* reflection)

r_2c = *combined* light from *sun and sky*, diffusely reflected from the upper outdoor surface of the adjacent sawtooth roof, to underside or ceiling of sawtooth in question and thence being again diffusely reflected to room below (two reflections).

The total amount of light entering the building and due to the summation of the above four elemental quantities is therefore

$$L = d + rd + r_1c + r_2c \ldots\ldots\ldots\ldots\ldots [2]$$

The author has derived the following approximate formulæ for determining each one of the quantities in Formula [2]:

$$d \text{ (per sq. ft. of } F) = \frac{aS_{x+y} \cdot \frac{180}{\pi} \cdot \frac{\text{vers } a}{a}}{F} \ldots\ldots\ldots [3]$$

where S_{x+y} = area of opening in lighting-area plane as defined in Part 1

F = floor area in sq. ft. over which light from area S_{x+y} is effective, that is, one bay long and a properly chosen assumed width selected for S_{x+y}

a = angle of light rays with lighting plane

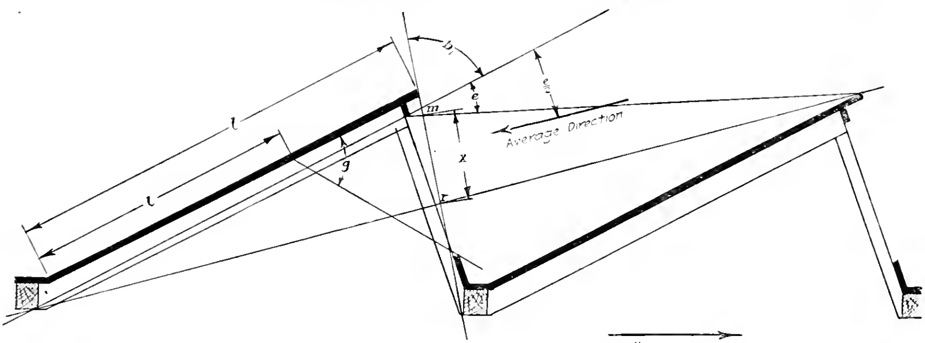

Fig. 3 Path of Skylight Reflected from Ceiling

$$= \frac{x\,\frac{b_1 + b_2}{2} + y\,\frac{b_1 + b_2}{2}}{x + y}$$

as will become evident by inspection of Fig. 2:

$$rd \text{ (per sq. ft. of } F) = \frac{R_1 D \frac{e}{2} S_g \sin\left(b_1 + \frac{e}{2}\right)}{F} \ldots\ldots\ldots [4]$$

[1] A full account of the trigonometric derivation of these formulæ is given in the complete paper.

where R_1 = coefficient of reflection of ceiling

D = proportion of reflected light utilized to total, which may be taken as

$$\frac{180° - g}{180°} \quad \text{(see Fig. 3)}$$

c = sky angle, Fig. 3

$b_1 + \frac{c}{2}$ = average direction of light rays;

$$r_1c = KS_1R_2P_1\left(d + \frac{rd}{R_1D}\right) \ldots\ldots\ldots\ldots\ldots [5]$$

representing average shade line on average day of year

P_2 = proportion of reflected light included between any vertical angle α, Fig. 5, from any point P

$$= \frac{\theta_2 + \theta_1}{2\pi} - \frac{\sin(\theta_2 + \theta_1)\sin(\theta_2 - \theta_1)}{2\pi(\theta_2 - \theta_1)}$$

and the other letters have the same meanings as in the preceding formulæ.

It will be observed that no reference is made to any particular standard unit of flux or intensity of illumination, and the formulæ

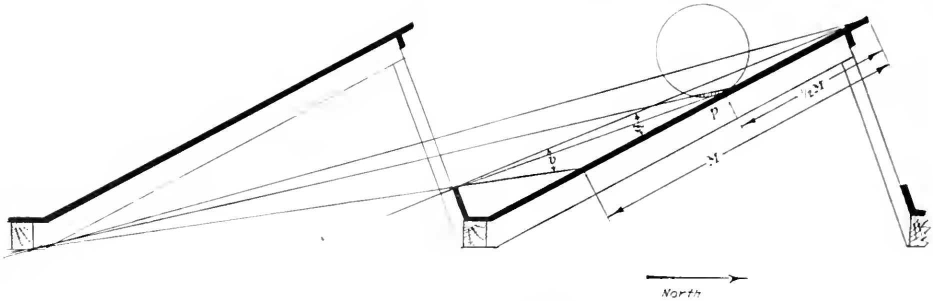

Fig. 4 Sunlight and Skylight Reflected from Roof Top

where K = average ratio of quantity of direct sunlight and skylight incident upon one square foot of roof surface as compared with the quantity of skylight only incident upon and passing one square foot of lighting area S_{x+y}

S_1 = ratio of effective roof area to lighting area S_{x+y}

R_2 = coefficient of reflection of roofing material

P_1 = amount of light obtained by reflection from roof, its proportional value included within any

give only the relative or comparative amounts of light furnished under their several respective headings.

The following example illustrates the method of applying these formulæ.

A Numerical Example, Diffused Daylight Conditions

Given the same typical sawtooth roof as in the example in Part 1, having angle of glass = 73°. *Required* to find the total amount of daylight entering, that is, quantity L, Equation [2].

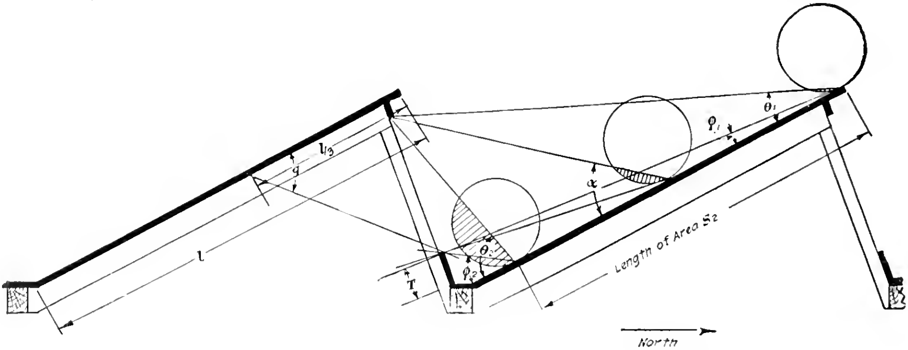

Fig. 5 Entrance of Sunlight and Skylight by Double Reflection

vertical angle g from any point P being represented by shaded portion of tangent circle in Fig. 4

$$= \frac{g}{\pi} - \frac{\sin 2g}{2\pi}, \text{ approximately;}$$

$d + \frac{rd}{R_1D}$ = quantity of direct sunlight incident upon and passing area S_{x+y} as determined by [3] and [4];

$$r_2c \text{ (per sq. ft. of } F) = KS_2R_1R_2P_2D\left(d + \frac{rd}{R_1D}\right) \ldots\ldots [6]$$

where S_2 = ratio of effective roof area to light intensity computed for roof area included between sawtooth ridge and a horizontal line part way down roof

To find quantity d, Equation [3]. From the detailed building sections, it is found that

$b_1 = 72° 30'$; $b_2 = 86°$; $b_3 = 80°$; $x = 44''$; $y = 22''$;

whence

$$a = \frac{44\frac{72.5 + 86}{2} + 22\frac{86 + 80}{2}}{66} = 86° 30'$$

and

$$\frac{180}{\pi} \cdot \frac{\text{vers } a}{a} = \frac{180(1 - 0.165)}{80.5\pi} = 0.592$$

Let the computations be based on a section of the sawtooth having a length equal to the width of one sash, i.e., 8' 3", the latter

having a net width of glass equal to 7′ 3″. The length of span between valleys is 17′ 0″. From the foregoing,

$S_{x+y} = 7.25 \times 5.5 = 39.9$ sq. ft. and $F = 17 \times 8.25 = 140$ sq. ft

Therefore entering Equation [3],

$$d = \frac{80.5 \times 39.9 \times 0.592}{140} = 13.6$$

TABLE 1 SHOWING VALUES OF x IN TERMS OF h AND (c)

$h°$	x for $c = 70°$	x for $c = 75°$	x for $c = 78°$	x for $c = 80°$
3	8° 11′	11° 03′	13° 50′	16° 30′
5	13° 28′	17° 59′	22° 18′	26° 16′
7	18° 29′	24° 28′	29° 52′	34° 36′
10	25° 30′	32° 57′	39° 24′	44° 32′
15	35° 28′	44° 01′	50° 40′	55° 44′
20	43° 15′	51° 55′	61° 05′	62° 43′
25	49° 15′	57° 36′	63° 20′	67° 22′
30	53° 59′	61° 49′	66° 59′	70° 34′
35	57° 36′	64° 58′	69° 41′	72° 56′
40	60° 30′	67° 22′	71° 42′	74° 40′
50	64° 36′	70° 43′	74° 30′	77° 03′
60	67° 15′	72° 48′	76° 12′	78° 30′
70	68° 49′	74° 05′	77° 18′	79° 22′
80	69° 44′	74° 47′	77° 50′	79° 52′
90	70° 0′	75° 0′	78° 0′	80° 0′

To find quantity rd, Equation [4]. From the detailed building sections, it is found as before that $b_1 = 72°\ 30'$; $x = 44''$; $e = 25°\ 30'$; $g = 40°$. Basing the computation on the same length of sawtooth as before,

$S_x = 7.25 \times 3.66 = 26.5$ sq. ft.

$F = 140$ sq. ft.

also,

$$D = \frac{180 - 55}{180} = 0.7.$$

Assume that ceiling of sawtooth roof is painted white and has a coefficient of reflection $R_1 = 0.60$. Then, entering Equation [4],

$$rd = \frac{0.6 \times 0.7 \times 12.75 \times 26.5 \times \sin(72°\ 30' + 12°\ 45')}{140} = 1$$

which is relatively small compared with d.

To find quantity r_1c, Equation [5]. From the detailed building sections, it is found that $q = 15°$

$$= 0.26 \text{ radians, whence } P_1 = \frac{0.262}{\pi} - \frac{\sin 30°}{2\pi} = 0.004.$$

According to a publication entitled *The Sun*, by Charles G. Abbott, S.M., Director Smithsonian Astrophysical Observatory, the average intensity of sunlight plus skylight on this sawtooth roof may be deduced as being during working hours, and for ordinary atmospheric conditions, four times that of skylight on the lighting-area plane. Therefore, let $K = 4$.

S_1 from the detailed sections is found to be 2.3. Assume the roof to be covered with clean white slag having a coefficient of reflection = 0.5. Therefore, entering Equation [5],

$$r_1c = 4 \times 2.3 \times 0.5 \times 0.004 \left(13.6 + \frac{1}{0.6 \times 0.7}\right) = 0.3.$$

This quantity, represented by Equation 5, is usually so small that it may be omitted entirely from the computations.

To find quantity r_2c, Equation [6]. From the detailed building sections, it is found that

$\theta_2 = 80° = 1.4$ radians

$\theta_1 = 24° = 0.42$ radian

whence

$\theta_2 + \theta_1 = 1.82$ radians, and $\sin(\theta_2 + \theta_1) = 0.97$

$\theta_2 - \theta_1 = 0.98$ radian, and $\sin(\theta_2 - \theta_1) = 0.829$.

Therefore,

$$P_2 = \frac{1.82}{2\pi} - \frac{0.97 \times 0.829}{2\pi \times 0.98} = 0.16.$$

S_2 is found to equal in this case 2.7.

$K = 4$, $R_1 = 0.6$, $R_2 = 0.5$, and $D = 0.7$, as before. Therefore, entering Equation [6],

$$r_2c = 4 \times 2.7 \times 0.6 \times 0.5 \times 0.16 \times 0.7 \left(13.6 + \frac{1}{0.6 \times 0.7}\right) = 5.8$$

Whence, Equation [2]

$$L = 13.6 + 1.0 + 0.3 + 5.8 = 20.7$$

This total quantity may be compared with a corresponding value computed for a sawtooth building already in service and of known degree of excellence as regards intensity of natural illumination.

In case additional illumination is required an alternate design having increased glass area or a flatter slope, or both, might be considered and in this connection it is interesting to note that if the pitch is decreased by only 10°, the glass area remaining the same, L figures out to be increased by about 15 per cent. On the other hand, assuming the building placed as in the first example and applying the principles of Part 2, it is found that considerable sunlight will enter for the entire day. That is, the period of total shade would be decreased on June 10 from more than 7 hr. to zero, direct sunlight being present continuously.

This information, when extended to comprehend that for other days of the year, including the day of average length, and when used in conjunction with the particular conditions and requirements of the problem in question (not excluding first cost), should facilitate the selection of the most advantageous design.

Various means have been adopted to exclude direct sunlight from the interior of such buildings, and all of them seem to have the disadvantage of reducing the total illumination. Sawtooth buildings with glass vertical, that is, with the effective angle of the lighting area actually *overhanging* are not uncommon; whitewashing the glass results in some protection against direct solar rays and a cooler interior, but also in glare and considerable loss of light.

Whatever glass is used, cleanliness is essential; furthermore the significance of Equation [6], indicating the possible average relative amount of reflected light, emphasizes the importance of adopting where practicable, light-colored roofing materials such as white slag, and also the use of white dust-resisting washable paints upon sawtooth ceilings of buildings in which maximum daylight is desired. If either of the above surfaces had been black, the average reduction in daylight for the second example would have been equivalent to 30 per cent, or, expressing it another way, the increased light resulting from their use amounts to over 40 per cent.

As before noted, Part 2 of the paper should be applied only with due regard to its practical limitations. It furnishes a means of comparison with known designs and is based on fair-weather conditions and with sunlight on the building as a whole. During cloudy weather the amount of useful light contributed from the top of the sawtooth roof is, of course, decreased, but, on the other hand, the quantity of direct skylight, which has been found to constitute the major portion of the total, is often thereby considerably increased.

Conclusions

From the foregoing analyses it is evident that the height of valley (T, Fig. 5) for a given construction should be made as low as is consistent with protection against the elements, including snow and ice.

Furthermore, it will be seen that for a given building the use of a *small* number of *large*-scale sawteeth as against a greater number of *smaller* units having the same pitch, results in considerably increased daylight due to fewer number of valleys of height T, and consequently less proportionate obstruction. This principle, of course, should be applied with due regard to the structural limitations and the architectural considerations which may be involved, together with the important question of uniformity of daylight intensity.

It is also worthy of note that the adoption (for the reasons above outlined) of flatter sawteeth with increasing terrestrial latitudes works out well in conjunction with the heating requirements, since it results in less cubage and radiating surface.

EMPLOYMENT OF LABOR

By DUDLEY R. KENNEDY,[1] PHILADELPHIA, PA.

MUCH concerning the description of the engineering and construction of the Hog Island Shipyard has appeared in various trade and technical journals. The labor requirements of the undertaking and the different phases of the activities undertaken in connection with the problem of securing employees and providing for their needs and comfort are explained in this article.

The contract between the United States Shipping Board and the American International Shipbuilding Corporation, Emergency Fleet Corporation, signed on September 13, 1917, called for the construction of the largest shipyard in the world and 120 ships, to be built therein, all in twenty-one months. Seventy of the boats were to be cargo carriers of 7,500 dead-weight tons and 50 boats of 8,000 dead-weight tons, combination cargo and transport.

The yard was to have 50 shipways, or two more than the six largest yards in America combined, with the necessary administration and service facilities to properly serve this number of ways.

The construction of the yard was practically complete on October 20, 1918. The following figures give an idea of what has been accomplished:

18 miles of streets and roads
82 miles of standard gage ballasted railroad track
21 miles of water pipe
50 shipways requiring the major portion of the 127,000 piles driven
72,500 ft. of drainage ditches
71,350 ft. of sewage piping
90,000 ft. of compressed-air pipe for the second largest compressed air plant in the world, the largest being at the Rand Mine in South Africa
16,300 ft. of fuel-oil pipe
A water-supply plant from which the plant is now using daily 2,000,000 gallons of water
250 buildings
15 large restaurants and cafeterias, serving daily 12,000 to 18,000 meals
4 ships have been launched
11 are under construction
61,000 tons of steel have been placed in ships
7,000,000 rivets have been driven
The bulk of 3,500,000 cu. yd. of material to be dredged has been removed and all of the divers and sundry things incidental and necessary to all this, which can be readily left to the imagination of a group of engineers familiar with such general problems.

All this has required the expenditure of much money. To illustrate more graphically just how much, and with what speed the job has progressed, it may be added, that the rate of money expenditures has been five times that of the Panama Canal.

In the inception of the job when the engineering estimates were in preparation, it was recognized that the labor problem would be one of the cardinal difficulties of the undertaking. Notwithstanding the difficulties, there were upon the payroll on January 19, 1918, 26,700 men, and there are now 35,000 employees. To obtain this number and maintain the necessary interim quota it has been necessary to hire a few more than 230,000 people in a calendar year. This means a labor turnover of nearly 700 per cent.

Let us see what conditions were when the job was started. Hog Island is situated about eight miles south of Philadelphia City Hall, upon the Delaware River, in a comparatively isolated spot, known principally for its shooting and its mosquitoes, inaccessible as far as regular transportation facilities were concerned.

At first, there was no passenger transportation into Hog Island by rail and how the employees traveled to and from Philadelphia is and will always remain largely a mystery.

[1] Employment Manager, American International Shipbuilding Corporation, Hog Island Shipyard, Hog Island, Pa.

For presentation at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 3 to 6, 1918. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis by members upon application. All papers are subject to revision.

Today there are two trolley lines, a steam shuttle line connecting with the main line of the Pennsylvania and the Reading, and an excellent train service over a special cut-off line of the Pennsylvania.

In the inception of the job, the management, appreciating the size of the "Human Engineering" phase, organized a department styled the Industrial Relations Department, having jurisdiction of the branches Employment, Medicine, Surgery, Sanitation, Safety, Housing, Feeding, General Welfare and Service and Compensation. Each of these will be described separately.

EMPLOYMENT DEPARTMENT

The manager of Industrial Relations ranks, with equal authority, with six other heads of departments, reporting direct to the President. This is an important point, as many companies now appreciate the importance of the "Human Machine" to a degree which places an executive in charge of Industrial Relations with authority paralleling that of executives in charge of other major phases of administration. This department occupies a two-story building 251 ft. long by 48 ft. wide, with an ell 132 ft. long by 63 ft. wide.

The Employment Department occupies the bulk of the first floor. The waiting room is 85 ft. by 48 ft. and will accommodate 800 men. The building was planned to afford as nearly a stream line or continuous process as possible through the various stages of the necessary employment routine; therefore the waiting room is situated at one end of the long face of the building. Immediately the applicant for employment finds for himself a place in one of six lines, formed before six doors, over each of which appears the name of the positions or jobs for which men are being examined in that "interviewing room."

In each of these six rooms is a man familiar with the specifications of the job or jobs for which he is selecting applicants, and into his room he receives in turn the men in line, and to each he gives a short, courteous, but adequate and firm catechising and determines his fitness for the position which he seeks.

Having accepted the applicant, he passes him on to the registration clerks, of whom there are about 25, who fill out a registration blank covering the many details which it is necessary to record for purposes of identification, for the State Workmen's Compensation Law, for the Selective Draft and for statistical purposes. This form when completed is handed the man and he proceeds to the physical examination, where he enters one of thirty booths and receives an examination in the nude to determine his fitness for work and for the particular job to which he is assigned.

Successfully passing this examination, the applicant proceeds to the photographic room, where he is photographed *with* his sequential employment number, which becomes his identification and payroll number, and his height and weight and date of hiring. This information is placed in a rack by lettered and numbered cards, and the new employee stands with his chin just over the rack so that the printed photograph shows all this information. This business of plant protection and identification has been perfected to such a nicety as to make possible the taking, developing and printing of 4000 of these pictures a day.

The new man is then taken to the Dispatcher and there the new men are grouped and taken by one of 15 messengers to the portion of the work for which they have been hired. When the messenger delivers a new employee to a department, the requisition issued the day previous is canceled, and the foreman signs a receipt discharging the obligation of the Employment Department.

The messenger is made necessary for several reasons, but principally because the plant covers 900 acres, has eighteen miles of streets and is $2\frac{1}{2}$ miles long and a mile wide, and it is quite a task for a newcomer to find his way about.

Medical Department

The Chief Surgeon is responsible for the medical, surgical, and sanitation divisions. The hospital equipment is the most up-to-date procurable and the hospital contains an anesthetic room, operating room, X-ray room, first-aid dressing room, re-dressing room, two wards containing 21 beds, dental clinic, eye clinic, heat-treatment room, etc.

In the month of August 1918 the plant had 7583 accidents, of which, however, only 160 were time-losing accidents of over one day. The percentage of accidents was only 0.97 per cent of the men employed, or less than 1 per cent, and the infections ran 1/8 of 1 per cent, all of which compares favorably with the best records shown by the largest commercial companies in the country.

Sanitation

Hog Island has all the problems of sanitation and hygiene of any city of 35,000. Working under plans of this Department, the mosquito has been absolutely eradicated and with it vermin of all kinds. The Department maintains a chemical and bacteriological laboratory which tests the drinking-water supply at all points of egress daily, analyzes sewerage, samples and tests all food served, and does all the work of the hospital on sputum, pus, excretions, blood, urine, etc. The Department maintains the medical dispensary, contagious hospital, and detention barracks, and its alertness and efficiency have made possible the phenomenal record of last winter as to the general health of workers, resident on the Island, and the record of the present influenza epidemic. For both, Hog Island records were as good as any shown by army cantonments.

Safety Department

The Safety Department is modeled along lines in general use by the larger corporations and the figures before quoted on accidents show that it has done its work well in so quickly bringing a "mushroom job" to the standards of the old-established corporations.

Housing Department

The Housing Department task has been trying, but barracks have been completed on the Island for 5000 employees, a bachelor hotel has just been opened accommodating 2200 men, with 2200 rooms. It is in fact the largest hotel in the world today. The E. F. C. has finished and is completing a unit of 953 homes of brick construction for married employees of Hog Island which rent for an average monthly rental of $25 for six rooms and bath.

During the last year the Housing Department has furnished 16,500 accommodations in the city of Philadelphia, and this in the face of the Philadelphia Housing Association's statement of a year ago that the city possessed not more than 5000 accommodations for the incoming human flood.

Feeding Employees

The Commissary Department is one of the most interesting on the Island. Its employees number 700, in 27 different units, the largest of which accommodates 3000 at a meal, and it feeds an average of 17,500 persons per day and during August of this year served 486,964 meals. The Department is run by the company for its employees without profit. Straight meals sell for 30 cents each, while the average cafeteria meal receipts are about 33 cents.

Service and General Welfare

The Service Department handles the matters most readily understood as welfare. These include the plant industrial Y. M. C. A., athletics, the plant weekly paper, and general services and welfare.

The welfare of the women employees is in the hands of a woman physician who fills the joint capacity of Welfare Director and Medical Advisor for them.

There are now employed over 2500 women. Most of these are in the offices in various capacities, and in the commissary department, but the employment of women for yard work has long since passed the experimental stage and women are working in our yards at 20 different tasks—from common labor to such skilled tasks as acetylene cutters and welders, and their number is being constantly augmented as the prejudices are being broken down and as the man-power shortage grows more acute.

Workmen's Compensation

The Workmen's Compensation for employees is administered by a branch of the Industrial Relations Department under the terms of the Pennsylvania Act.

The wage setting and adjustment for the job has been a serious task, and while the U. S. Shipping Board Labor Adjustment Board has fixed a standard scale for all shipyards, covering the shipbuilding trades, the construction of Hog Island presented many problems on construction rates involving almost every conceivable craft. Notwithstanding the hardships to which workmen have been subjected, and the difficulties with which the works has been beset, not one day has been lost through strike or labor difficulty. The "open shop" has maintained throughout and it is only justice to say here that organized labor has, in the main, lived up to its agreement with the Government in not attempting to force recognition or the "closed" shop.

Almost the universal problem with employers has been the question of securing a sufficient number of employees to operate at maximum capacity. It has been a question of "collection," not of "selection."

INDUSTRIAL ORGANIZATION AS IT AFFECTS EXECUTIVES AND WORKERS

By CHARLES E. KNOEPPEL,[1] NEW YORK, N. Y.

THE object of this paper is to establish some rules of efficient organization for the practical guidance of executives in developing an intelligent system of industrial relationship. Now more than ever, after so many years of war, it is required to direct every effort to increasing industrial production and promoting international trade, in order to coöperate in the tremendous task involved in reconstructing the world.

Three facts must be borne in mind in connection with the problem of industrial relationship: Industry is nothing but the collective action of various individuals; management consists of controlling and guiding the acts of the different agents engaged in industry; and industrial relations are the reactions created in all individuals, as a result of this control or guidance on the part of the management.

The flow of influence in relationship is from the administrative executives to the operating heads, to the superintendents, and finally to the workmen. In order for this influence to operate successfully there must exist a system of proper coördination

[1] President, C. E. Knoeppel & Co., Assoc-Mem.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

among the various agencies in industry. Well-defined policies in the executive branch of an administration secure contentment and satisfaction in the workers.

The following suggestions are offered in an effort to formulate a code of practical laws of efficient organization:

The Objective

A tentative plan of organization should be worked out and decided upon. Owing to the presence of unknown factors, which cannot be determined in advance, the ultimate objective cannot be agreed upon at the outset; in fact, it will be well toward the completion of the work before the final type of organization can be settled upon. No plan can be worked from the top down in its entirety, nor should one be worked altogether from the bottom up, for this would result in a development lacking coördination. The game should be one of "playing the ends against the middle."

Greatest Complication

A department should be divided into the most difficult functions which the men in charge will be called upon to undertake. The evolution of industry from a one-man stage to that in which many men are needed for the handling of specific things, has been based, consciously or otherwise, on this "law of greatest complication." In manufacturing, for instance, there was no doubt a time when the same man could both design and sell what was to be made and then go out in the shop and make it. But as the knowledge required of a man to design, sell, and to make, became greater and more complete and intricate, it became necessary to form two sections or departments, each of which took over one of the functions named above. Each department was placed in charge of a specialist, and both departments were supervised by the man who formerly handled all the details himself.

This law that is involved applies not only with reference to a business as a whole, or to a single department of a business, but to any division of any department.

There are several reasons for establishing this law: First, to guard against putting more work on the shoulders of a man than he has the knowledge and ability to handle; second, to make it possible to pick out the hardest job first; to make possible the selection of that work which will yield the greatest returns in the shortest possible time.

Concentration

Each section, division, or department of a business should be so arranged as to contain all the factors which will effect the performance of only its own function. If such a plan is adopted, the head of the work can be held strictly responsible for the successful conduct of his department, as he controls all the factors in connection therewith and can therefore be given to understand that he will stand or fall according to his showing.

The strict observance of this law when organization is being effected greatly reduces the amount of supervision required, and also tends to develop and strengthen the men in the concern. If a man is given full charge of a division or section of a business, and controls every factor that affects the successful performance of the main function of that division or section, he can be held wholly responsible for that function. If, however, other men besides himself have charge of some of the factors affecting the success of that function, it is impossible to hold him solely responsible for it. The only method of supervising him, under such circumstances, will be to hold him responsible for all the operations in his charge that affect the performance of his function, and then to check him up carefully. Such a system involves an excessive amount of work in supervising, and also forces the man himself to follow personally all the details of the work he supervises, in order that, when called to account for them, he may be familiar with their condition. Any one, under such a handicap, will naturally become absorbed in details, to the detriment of his executive work.

Individualism

A battle cannot be won by half a dozen generals, all of whom have equal authority. There must be one-man control.

There is nothing more confusing in an organization than for employees to have more than one man to whom they are directly responsible, and nothing that so quickly destroys discipline as to have a manager go over the heads of his subordinates. Yet these are among the faults we find most frequently in organization work.

When a man enters an organization, his duties and all matters which he is to be held responsible for should be definitely stated to him. In addition, he should be told who the head is to whom he is responsible for carrying out his duties, as well as who the men are that will be responsible to him.

Mutual Capacity

When a department or business is reorganized, a division should be made with reference to the knowledge and ability that will be required of the man who shall supervise the work, as well as with respect to the knowledge and ability that those men must have who shall actually carry out the work. Then, too, what is to be done must be within the capacity of the average types of men who are fitted to fill the various positions.

If an organization is divided according to its most difficult function so that the knowledge required for each position will be as little as possible, and the positions are arranged so that each executive has complete control of all the factors affecting the success of his function, the executive jobs, as a rule, can be well handled by average men. If, however, the organization is incorrectely divided, and each executive is given a slice of this and a part of that, and the success of each man's job is dependent on the successful handling of a lot of work that is handled by other executives, then there will be great difficulty in obtaining executives who can produce satisfactory results. Even if the company, under such circumstances, does hire executives of proved ability, they will soon deteriorate under the bad form of organization, will lose all their initiative, and will become worthless in a few years.

Specialization

An organization should be divided so as to develop specialists. To this end, care must be taken that one department head shall not duplicate the work of another.

Specialists are developed by allowing men to work in a limited field of knowledge. In other words, a man is so developed that instead of knowing many things superficially, he will know a few things extremely well. If the knowledge necessary to manufacture and market a number of products is divided up into a number of limited fields of knowledge, as it were, and one man is put in charge of all the work in each of these fields of knowledge, these men will become specialists. Now if, under each of these men, each of the sub-heads is in charge of all the work representing one portion of that field of knowledge, then there is an organization of specialists.

In an organization of specialists there is no difficulty in finding men to fill competently executive positions, for the average man with executive ability can handle efficiently a large amount of work in a limited field of knowledge.

Responsibility

An executive should be held responsible for the total proven results, or for inability to secure results, and not for the details of the methods that he uses in trying to secure these results.

It is a frequent fault in organizations that the bigger executives—especially those who, when the concern was small, followed all details—judge the executives under them by various details that they find wrong, instead of judging them by the total proved results in that section of the business for which those minor executives are directly responsible.

Permanency

What would happen if, during an engagement, a member of an artillery squad, or of a gun crew on a battleship, should suddenly be killed, and none of the others should know what to do in his place? The consequences would be serious indeed. And yet in industry we find many cases in which no provision has been made for training men to fill the positions of their superiors, in case anything should happen to the latter. A man may at any time be transferred, or he may die, or be taken sick, or resign his position, or take a vacation, or be dismissed from the employ of the company. In any of these cases, it will be the duty of some one else to fill the gap at least temporarily, perhaps permanently, and if no one has been trained to take over the new work, results are bound to be unsatisfactory, if not disastrous.

Relationship

A business is nothing more or less than the adjustment of individuals, to the end that all may follow a definite policy, or line of procedure. One of the weaknesses in business is the almost universal practice of giving an individual only the most general kind of instructions concerning what to do and how to do it.

A man is engaged to do a definite "something," and just what that something is should be known by all with whom he comes in contact; otherwise he cannot be held responsible for results. His functions in the business, his duties in performing this function, and his relation to others and of others to him, should be sufficiently defined so as to enable him to work efficiently.

Personnel

A set of specifications covering the qualifications required in each of the members of the personnel should be determined before making their selection. Hiring men is, or should be, like purchasing materials, in that there should be, first of all, definite knowledge of what is required. After all, it is a case of matching qualifications against requirements. If we know what we want, we can check the merits of the material that we examine. For instance, if a position demands close application, long hours, and indoor work, it is sheer folly to engage a man who loves the open and therefore detests confinement and close application. He would naturally be inefficient because discontented and unhappy.

If it is essential in buying a machine, to lay down certain specifications, and then make sure that the machine measures up to them, it is just as important to have specifications in regard to the men we shall engage, in order that we may check their qualifications against them.

Instructions

A ship without a compass would not be used in ocean transportation; a boiler without a safety valve would not be used in a steam plant. And yet in industry there is little, in many plants, that corresponds to compass and safety valve; or, in industrial terms, there is a lack of instructions and charts.

Anything worth defining is certainly worth recording and yet we have all seen organizations of people working together without any guide whatever in the form of standard practice, no definite idea of functions and duties, no charts showing relationship. The difference between having such charts and not having them is simply the difference between organization and disorganization.

The concern that insists on properly issuing complete written information covering the material it buys or the product it sells, will deem it unnecessary to have written instructions and charts covering the operations of the people who use the material and make the product.

Staff

The chief of staff should be a man of experience, tact, and exceptional analytical ability. Every department manager should have the right to call on the staff to assist him in the solution of his problems, and to have them make detailed studies of any sections of his department that are not running satisfactorily. If the managers can be induced to make such calls on the staff freely, the results obtained will be satisfactory, but if staff advice has to be forced on them the results will be poor. Staff consultation should never be forced on a manager except when the reports from his department show decidedly poor results and he does not call on the staff for assistance. In these cases it should be suggested that the staff assist him, and if he refuses to take the suggestion, he should be forced to accept their coöperation.

Functions of an Executive

The functions of an executive should be: To exercise general supervision over the business or the department; to analyze results critically; to put new problems before his men for their consideration, advice and action; to criticize subordinates when results are not forthcoming, explaining the reason why; to see that the prescribed practice is regularly followed.

An executive should not attempt to do everything himself, but should deputize authority among competent assistants. He should not waste time over minor details, and, most important of all, he should study men in order that he may be able to arouse in them the greatest possible amount of initiative.

If the solution of the present economical problems is ultimately dependent on the successful development of industry, and this can be achieved only by efficient organization, it is the duty of every industrial community to take the steps necessary for securing an undisturbable harmony between its various social elements. By the coöperation of capital and labor, with a perfect understanding between the employer and the employee guided by a sense of justice and fair dealing, industry will contribute mightily to the progress of the world.

LABOR DILUTION AS A NATIONAL NECESSITY

By FREDERICK A. WALDRON,[1] NEW YORK, N. Y.

THE term "Labor Dilution" originated in England shortly after the declaration of war with Germany. Its original application was intended to carry out in effect what the definition of the word "dilution" literally implied; namely, a thinning or spreading out. As applied to labor, it means the thinning out or spreading of the functions of the skilled workmen among those that are less skilled, and a Bureau of Labor Dilution was therefore established by the Government to supervise and carry out its requirements.

The original objective of this bureau was to relieve the skilled workman in the performance of certain functions of a task and employ less skilled workers for the purpose of accomplishing a given task in a shorter time.

The development of the work of this bureau has been such that economies heretofore unknown have been established and the fact brought before the manufacturer in evidence strong and beyond contradiction that many things done for apparent necessity were not at all necessary to the proper and efficient conduct of busi-

[1] Industrial Engineer, 37 Wall St. Mem.Am.Soc.M.E.

ness. Its work, during the war period, will become a national industrial asset and change the entire mental attitude of the employer and the employee to one of greater coöperation and higher efficiency for years to come

Unintentionally, perhaps, and unconsciously this bureau has created an element in labor dilution which was not included in the original program, as it has already established in the minds of the consumer that waste of labor and materials is the greatest foe to labor dilution that a nation may have.

This is a vital problem, and it is the engineer who must solve it in a scientific and satisfactory manner. For years following the war our work must be done in the spirit of conservation, with profits a secondary consideration. This involves the engineering of men in the broadest sense, since the supplies of both have become so seriously depleted through the waste of war.

Ultimately it will be the "survival of the fittest." A nation's industries must be those for which it is particularly adapted; they must be conducted in the most economical manner, and facilities for vending and transporting their products must be on an equally economical basis. For products of equal quality, those having the lowest unit costs will naturally maintain commercial and industrial supremacy. The nation which can deliver to the consumer its converted natural resources in the minimum of time with the least expenditure of human energy is the nation which will lead the industry and commerce of the world.

To accomplish this there must be a broad and comprehensive national policy in the organization of our legislative, banking, business, agricultural, transportation, mining and manufacturing policies.

As the value does not appear until labor has been applied to nature's labyrinth of wealth, it is incumbent that the study of labor requirements and performance be given most careful consideration, and to this end it will be helpful to summarize the conditions which confront us at the present time, as follows:

1 The equipment and physical condition of our transportation facilities are not being kept up to the pre-war condition of efficiency
2 Agricultural industries are suffering for the lack of labor and intensified productivity of soil
3 Our roads and highways are rapidly deteriorating due to the lack of man power to construct new and repair the old roads
4 Work on the enlargement and development of public utilities is practically at a standstill
5 Irrigation projects are practically stopped
6 The manufacture of munitions, when abandoned, will place an immense amount of machinery in the scrap heap. This must be replaced by new machinery
7 Operations in the erection of buildings other than those required for immediate war needs has practically ceased
8 The output of our steel mills has been practically absorbed by the Government for war work
9 Immigration has practically ceased
10 The birth rate will supply but a small percentage of the man power needed.

From the enumeration of the above items, it can be fully appreciated that the accumulation of work to be performed is stupendous. Therefore, if our present methods continue, the great problem will be to obtain labor for this work.

It is self-evident that we cannot depend on European immigration to this country for this period. The depletion of man power due to war losses and the demand for this power in the reconstruction period abroad, combined with the internal development that is likely to take place in Russia, will mean that immigration from these countries will be prohibited. Further, of the man power sent by this country to Europe, at least ten per cent will be incapacitated for work of a strictly laboring character.

We will, therefore, be practically dependent upon native-born Americans based on our population of 1900 to 1905, which is estimated as 90 to 95 million. The best available statistics at the present time would indicate that the average birth rate of this country is 25 per thousand population and that the death rate is 15 per thousand, leaving a net gain of ten persons per thousand. This means that there will come to workable age in the post-war period about 900,000 yearly, of whom approximately 400,000 will be males.

While the employment of an abnormal number of females as a war measure is right and justifiable, its continuation during the post-war period is problematical from the standpoint of the nation's man power.

This brings the subject of Labor Dilution as a National Necessity to a phase much broader in its meaning than that which was originally intended.

Broadly speaking, labor dilution should consist not only in the functionalizing of the work of the skilled man with that of the less skilled man, but it is equally important to eliminate useless and unnecessary labor which, at the present time, is deemed necessary due to the mental attitude and the habits formed in years of development and peace. It would seem, therefore, that the problem of labor dilution can best be approached by classifying into the following program:

1 Standardization (indirect); (a) Legislative methods, (b) business and financial methods, (c) transportation methods, (d) mining and agricultural methods, (e) manufacturing methods.
2 Coöperation (indirect): (a) Legislative methods, (b) capital and labor, (c) engineering methods.
3 Elimination (direct): (a) Non-essential statistical work and data, (b) non-essential office work, (c) non-essential administrative work, (d) non-essential sales and advertising work, (e) the idle citizen or loafer.
4 Education (direct): (a) Of the legislature, (b) of the business man, (c) of the engineer, (d) of the executives, (e) of the laborer.
5 Occupation (direct): (a) Analysis, (b) distribution, (c) localization, (d) compensation.

Standardization (Indirect)

While the final effect of standardization on labor dilution is indirect, this is the foundation on which it should be built. The principal divisions are outlined above and will be briefly analyzed in the order of their importance.

a Legislative Methods. All laws regarding the conduct of business should be simple and direct, and the purpose in view should be the eliminating from the honestly conducted business, complications or hardships involving unnecessary expense and red tape; such laws to be drawn up with the hearty and consistent coöperation of the legislator, the business man and the employee, with the view of making them as simple and direct as possible. With honesty of purpose and fair dealing on the part of all, there should be no serious difficulty in establishing laws that would be much more simple and uniform than those at present in force.

b Business and Financial Methods. Where there has been rapid growth and an immense volume of business, it has necessarily carried with it an enormous labyrinth of complication, duplication and detail work which requires the employment of a large number of non-producers to care for records necessary to bring the raw material to the consumer. The result of standardization would, in a measure, automatically eliminate this labor and tend to reduce the cost of doing business.

c Transportation Methods. The amount of labor involved in the transportation of raw material to the consumer, directly or indirectly, is enormous. By the adoption of standard forms, carriers, and an improvement in the vehicles of transportation, with improved methods of handling materials at the terminals, a great amount of labor would be liberated for other work.

d Mining and Agricultural Methods. The amount of labor employed on this class of work could be greatly reduced by the introduction of new machinery and the perfecting of existing machinery. In mining great progress has been made in the reclaiming of what was once considered waste ore. Certain strides have been made in the agricultural field whereby the productivity per acre of ground has been greatly increased. This practice, however, has not been employed in a large number of the small

areas under cultivation. Intensive mining and farming should be given more attention.

e. Manufacturing Methods. The standardization of production in our factories would eliminate a large amount of surplus materials which are now carried in stock by the dealers, and would allow of interchangeability of parts that are most essential and enable business to be transacted direct with the consumer. This would reduce the inventory investment of manufacturers and dealers, thereby reducing the number of pieces to be made and the labor applied thereon.

Coöperation (Indirect)

It naturally follows that, in order to obtain the benefits from standardization, coöperation should obtain to the fullest extent; and by continuous and systematic effort on the part of the legislator, the business man, the engineer and the workman, the essentials under the head of Standardization would begin to produce results.

Elimination (Direct)

The natural results following standardization and coöperation would be elimination, since many employed at the present time would necessarily be transferred to other lines of occupation.

The general headings covering the classes of work eliminated are included in the preceding classification.

Education (Direct)

Following standardization, coöperation and elimination there should be a concerted effort to educate to a new epoch of economy. The term Education as applied to this particular phase of the situation is used as an expression for the change of the mental attitude of the public from that of extravagance to that of basic economy. It should teach that "waste makes want and want makes woe," and that the conservation of our present energy and natural resources is of greater national value than the unlimited accumulation of the almighty dollar.

Occupation (Direct)

Last but not least, occupation should be considered in the problem of labor dilution. An era is approaching in which the conditions of the present and past will be entirely changed and which will involve a wholesale change in the distribution of occupations.

In order that this may be done with the least disturbance, a careful analysis should be made of the adaptability of the individual to the occupation, and consideration should be given to the distribution of such occupations. Coincident with this should follow the locating of industries at such points as will insure economic production.

The occupational problem that will ensue will always lead to differences of opinion, but it is governed largely by supply and demand and the standards of living in different communities or nations. The lower the standard of living, the lower the compensation for labor. The higher the standard of living, the higher is labor compensated. The problem, however, resolves itself into the production and delivery to the consumer at the lowest possible cost with a fair profit to the manufacturer.

These are facts showing that "a condition and not a theory" confronts us. If it is expected to keep in circulation the currency of the world at the present rate, it is necessary that public improvements, manufactories, agricultural and mining interests should continue at a rate commensurate with the present circulation of money.

This means a gradual readjustment, and, in order to be prepared for this readjustment, the problem should be looked squarely in the face and the way paved by which such readjustment can be made with the least possible disturbance. This can only be done by careful planning and action on the part of the country's greatest men in preparing to meet the problem of labor dilution in a broad way.

The English, with their customary conciseness, have expressed in the two words, "Labor Dilution," that which it would require volumes to describe or discuss.

A study of the problem indicates that, in its broadest meaning, Labor Dilution and the Engineering of Men are practically synonymous, since the former involves all that the latter implies.

USE OF NON-FINANCIAL INCENTIVES IN INDUSTRY

By ROBERT B. WOLF,[1] SAULT STE. MARIE, ONT., CANADA

THE basis of all "non-financial incentives" is interest in work. Interest in work implies a desire to produce, actuated by internal motives rather than external discipline.

Production means creation, and the industrial creative function in man is a mental process and lies in his intelligent adaptation of means to ends. It is useless, therefore, to look for real creative work unless the workman has a chance to think and to plan; any other working environment either fails to attract or actually repels the workman, and as a consequence offers no incentive to increased effort.

Work which does not call for thoughtful reflection and which uses only muscular effort tends to draw men down to the level of the brute and makes for industrial irresponsibility and consequent social disorganization. The unthinking man cannot be a responsible man.

It is the self-conscious faculty of man which distinguishes him from the animal and makes him, above all, a creative center through which the universal life-giving power can deal with a particular situation in time and space.

To use a homely illustration with which every one is familiar, the traffic at each crowded street crossing cannot be regulated from the City Hall; it requires an individual (the traffic policeman) in the congested spot to deal with each particular situation as it arises, and upon his powers of observation and selection depends the orderly flow of traffic.

It is only through the individual life that the universal life can act, and therefore the universal is compelled to evolve many individual lives if organization and order is to replace the unorganized state represented by the purely generic operation of natural law.

The problem of social organization is, then, how to organize society upon the basis of respect for the individual. This is also the industrial problem as well, for industry in the broadest sense is society in its highest form of activity because it is essentially constructive and therefore creative activity.

It was an inevitable corollary to the universal plan of creation that the individual life came into being, not to create material substance as that had to be before individual life could gain consciousness. The function of the individual life, however, is to create by a thought process conditions especially selected to produce results which nature unaided would find herself unable to produce.

This is what the horticulturist does. His power lies in his knowledge of natural law, and his creations are made possible because he conforms to the law. The uncultivated orchard reverts to its original wild state when no longer attended by man, but increases in productiveness by continued thoughtful application of man's power of selection and adaptation.

It is by a similar process of conscious selection that such devices as the steamboat, steam engine, electric generator and the

[1] Manager, Spanish River Pulp & Paper Mills, Ltd. Mem.Am.Soc.M.E.

telephone came into existence. They did not come into being, and never would have been created by the generic operation of nature's laws.

* * *

The creation of artificial conditions, which, taken all together, we call civilization, is, of course, the product of man's organizing power. While self-consciousness, the power of realizing the self as apart from the rest of the universe, has been a human faculty for untold ages before the present highly organized state of society had been attained, it is nevertheless true that now, for the first time in the history of the white race, we are confronted with the problem of correcting the repressive or selfish character of civilization so that it will serve the mass of humanity. If we fail to accomplish this it will be destroyed by the same creative power which brought it into existence.

We must learn how to change the industrial environment from one which repels mankind to one which attracts. In other words, the incentive to work must be inherent in the nature of the work itself.

Now what are the conditions which we must meet in the industrial world to make work attractive? We have ample evidence that increasing financial returns have failed to stimulate productivity; and, on the other hand, the constant demand for shorter hours and the increasing labor turnover is proof that work in most of our industries not only does not attract, but actually repels, the workman. We must, therefore, look into the working conditions themselves for the answer. This is the only scientific method of procedure.

* * *

It can be shown that creative work can be done to a great extent in modern industry, and that it can be accomplished without radical changes in equipment, greatly to the advantage of both employer and employee. To do this, individual progress records are necessary, so that the workman can know from day to day how he is improving in the mastery of the process.

The first example, illustrated by Fig. 1, is from that branch of the wood-pulp industry known as the sulphite process, and shows a cooking chart which was designed to give the cook information about the reactions in the digesters in which the wood chips are cooked in a 6 per cent solution of sulphurous acid partly combined with a lime base.

The digesters have a conical top and bottom and are usually 50 ft. high by 15 ft. in diameter. After the acid and chips are put into the digester and the cover is put on, steam is turned in at the bottom and the pressure brought up to 75 lb. per sq. in. above atmospheric pressure.

As this does not heat the digester sufficiently to produce disintegration of the wood, it is necessary to relieve gas through a relief valve on the cover. Because of the removal of this gas, which is afterward reclaimed, more steam can come in at the bottom and thus the temperatures are advanced. The skill in cooking consists in the proper control of the relief valve.

Before the introduction of these cooking charts illustrated by Fig. 1, all this was left to the unaided judgment of the cook, with usually nothing to help him but a small hand thermometer and a pressure gage. Of course, great variation in the pulp was the result. The cooking charts, plotted by the cooks themselves, however, helped greatly as they enabled the quick visualization of the work. On these charts temperatures are converted to pressures for the reason that the pressure in the digester comes from two sources, one the natural pressure due to steam, and the other due to the sulphurous acid gas.

* * *

At the end of the cooking process the gage and steam pressures will naturally come very close together, as the greater part of the SO_2 gas has been used. The gas pressure curve is obtained by subtracting the steam pressure from the gage pressure. It is really a resultant of the other two. If it drops too rapidly the cook knows he is relieving his digester too hard and checks the opening of the relief valve. If it does not drop rapidly enough he knows he must open the valve wider in order to increase the relief. Of course, the figures are taken from recording instruments which are checked daily to insure accuracy. Naturally, an ideal cooking chart was soon formed, being the joint work of the cooks handling the digesters and of the chemical research department.

Immediately after the introduction of these charts a very marked increase in the uniformity of the pulp was noticed, and the cooks, while at first opposed to the new method of "cooking with a lead pencil," as they called it, soon learned to like their work much better for the reason that they now had some way of visualizing the work in its entirety.

In addition to more uniform quality of the pulp, the yield from a cord of wood increased something over 5 per cent.

We soon found that it was necessary to give some sort of continuous progress record if we were to keep up the interest in the work, because no man could carry in his mind anything but a

general impression of his progress from day to day. Several good records for one day are only like so many good golf drives. They are a source of satisfaction at the time; but just as the score in golf denotes our real mastery of the game, so does the progress record measure the man's increasing mastery of his work, and we feel that it is one of the moral obligations of the management to keep such records for the individual workman.

* * *

Such records can be grouped under three main headings: quantity records, quality records and economy or cost records. Quality records, which occupy the middle position, are, perhaps, of the greatest importance, for they bring the individual's intelligence to bear upon the problem, and as a consequence, by removing the obstacles to uniformity of quality, remove at the same time the obstructions to increased output. The creative power of the human mind is, however, not content simply to produce the best quality under existing conditions of plant operation. The desire to create new conditions for the more highly specialized working out of the natural laws of the process demands expression, and this expression at once takes the form of suggestions for improvements in mechanical devices.

This desire contains within it the germ of economic thought which will unfold and express itself eventually in a request for cost records, and the organization that neglects its opportunity to satisfy this desire is overlooking one of the great avenues leading toward intelligent productive effort.

Because of the interrelation of quality, quantity and economy records, any complete record of individual progress must, of course, take them all into account. However, as this is not always practical, we have at least one of three ways of measuring progress always open to us.

Table 1 shows how we keep a continuous progress record of the work, which is mainly one of quality. By quality I do not necessarily refer to the quality of the material produced, as most of our records refer to the quality of the work performed: in other words, the nearness to which the workman approaches the ideal standards which he has helped to form. The democratic coöperative forming of these standards by the joint work of the trained technician and the practical workman is absolutely essential, otherwise continuous progress will not be made. The whole plan must be really educational in nature, and to be so the records must record the natural laws of the process and the individual's degree of control of forces in the material elements that he is using. The more factors that can be recorded, the greater the interest in the work. The reason for this is obvious.

Referring again to Table 1, it will be noted that there are nine men cooking. These men are posted in the order of seniority, with the highest monthly record on top. There are three foremen at the top of the record. Each of these foremen has three cooks under him, and their standing is made up by taking the average records of the men under them. In this way we are enabled to get not only the individual records of the men, but the group, or teamwork records, as well. The lower group is merely for the convenience of the department head in charge and gives the relative standing of the large, medium and small digesters. This is irrespective of the men who are working on them.

The total progress record figures in the first column are made up of the temperature, color, time and blowing records. The relative values that these have in the total record are shown at the top of each column, the total adding up to 100. The small variation in the monthly average column is characteristic of all our progress records, and shows how great is the incentive when individual effort is intelligently recorded.

The temperature record is obtained by taking half-hourly readings from the recording-thermometer chart, upon which a standard temperature curve has been plotted, calling each reading which happens to fall on the standard line 100, and a reading 20. deg. either side of the standard line 0. For each degree off of the standard, 5 points are deducted from the progress record.

The color record indicates how near the men come to blowing the digester when the color of the liquor shows the proper amount of lignine in the solution. The sample, drawn from the side of the digester, is compared with the standard color. To get a mathematical value for this factor, a range of colors from a very dark to a very light was obtained, the particular shade which was taken as standard marked 100 and one shade either side 10 points less than 100.

The time record is obtained by calling a certain time of cooking 100, and taking off on each digester cooked one point for each minute above or below this standard.

The blowing record is obtained by calling 30 lb. pressure 100 (most of the cooking being done at a pressure of 75 lb. per sq. in.) and 60 lb. 0, the idea being to get the pressure as low as possible before blowing the digester.

It will be noted that the temperature value is higher than any of the others. This is because it is the most important element. The color record coming next in importance is given the next highest value, etc.

* * *

In the plant where this system was developed were employed over 1200 men, and perhaps half of these men had individual progress records and the rest came under some sort of group progress record. Invariably the records proved themselves to be an incentive to greater productivity.

* * *

Fig. 2 shows the concrete results obtained by giving the cost sheets to the department heads and job costs to the maintenance foremen. There was a rapid increase in production from 1908 to 1913, also a rise in repair material used, as well as an increase in the cost of maintenance labor. The fourth curve, showing the amount of material used for each dollar spent for maintenance labor, is more or less a resultant of the other two. The gradual rise from 1908 to 1911 in this curve was due to the increased material-consuming power of the maintenance men because of the introduction of labor-saving devices, such as pneumatic and electric portable tools. There was a drop in this figure in 1912 and 1913, but we were unable to get a real thought of economy started in the plant until the departmental cost sheets and job cost sheets were started. These were put into effect first in the beginning of 1914, and there was an immediate drop in the curve from an average of about $2.35 worth of material spent for each dollar spent for labor, down to $1.55 in 1914 and $1.05 in 1915.

The drop in production in 1914-15 was due to war conditions which were unavoidable. It is a significant fact, however, that in spite of this drop in production the maintenance material cost per ton of pulp was reduced to approximately half the amount under

the conditions of higher production during the two preceding years.

In none of this work did we pay bonuses to a superintendent, department head or workman; our salaries and wages were high, but payments were all on a monthly, weekly or hourly basis. The increased effort, therefore, came entirely from a desire within the individual to be productive. Of course, this sort of creative effort produced great changes in operating conditions—we increased our yearly production from 42,000 tons to 111,000 tons without adding to the number of digesters for cooking the pulp, or wet machines for handling the finished product, and we changed our quality from the poorest to the very best.

* * *

We should never lose sight of the fact that the degree of conscious self-expression which the workman can attain is in direct proportion to the ability of the organization to measure, for his benefit, the impress of his personality upon it. The most democratic industrial plant, therefore, is the one which permits the fullest possible amount of individual freedom to each member, irrespective of his position, and at the same time is so sensitively adjusted that it reflects immediately the effects of his actions. If his actions result in injury to others he will see that as a part of the whole he, himself, must also suffer.

* * *

Man is not an animal, but a free, self-determining mental center of consciousness whose reason for existence is that the universal life can deal with a particular situation in time and space, and by this means be enabled to evolve a material universe organized to express the one great individual life of which we are all a part.

In conclusion let me say that I am well aware that to some of you this may seem like pure philosophical speculation far removed from the practical affairs of everyday life. I have said nothing, however, that I cannot back up by any number of additional illustrations, and my hope is that the examples given will stimulate others to make similar investigations, so that we can fulfill our mission in this country by evolving an industrial philosophy which will have for its ultimate aim the continuous unfoldment of the latent powers in man.

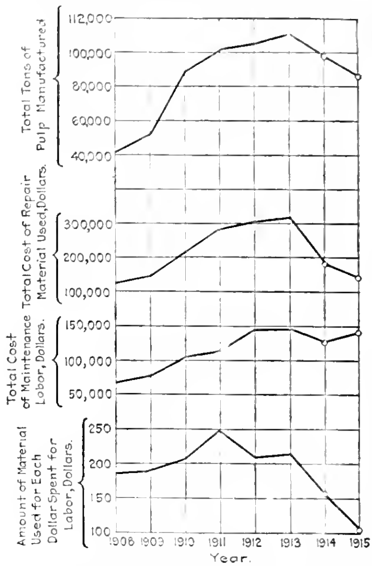

Fig. 2 Showing Concrete Results of Cost Sheets

UNIFORM BOILER LAWS

By E. A. BROOKS,[1] ATLANTA, GA.

In 1914 there were between five and six hundred people killed outright, some fifteen hundred injured, and several millions of dollars in property and production lost in this country through the needless explosion of boilers. I say "needless" explosions after due consideration, for it is a fact that the majority of these occurred where the boilers were not subject to regular inspection either by the state or by insurance companies.

One experience is enough to convince any one that safe boilers are altogether desirable. One morning when passing down a line of boilers in my charge I was startled to observe that the steam pressure on one boiler was 300 lb. per sq. in. It developed later that one bright water tender had, through ignorance, oiled the safety valves! Of course the oil evaporated and stuck the safety valves to its seat. But knowing this did not help the situation at that time one bit, but what did help was the fact that the boiler was built with a *safety factor of five*, as is prescribed by the A.S.M.E. Boiler Code.

There has been a strong feeling all over the country for proper legislation along the line of safer boilers. Our Society felt this need and set its wonderful resources to work to formulate laws for this purpose, which, while providing a maximum of safety for the users and public, would not in any way put an undue hardship upon the boilers. This was completed and is now known as the A.S.M.E. Boiler Code. It has been conservatively estimated that this code, if paid for at consultation rates, would have cost $250,000.

As The American Society of Mechanical Engineers is precluded from engaging in public campaigns relating to legislative matters, The American Uniform Boiler Law Society was formed to secure the adoption of the A.S.M.E. Code in its entirety in the various states and to promote the manufacture and sale of safer boilers. This new society is an organization of boiler manufacturers and users and as far as possible is representative of every branch of the boiler industry.

The enactment of boiler laws by the various states is not new at this time. Through the influence of the members of this Society and others the state of Massachusetts passed a bill governing the use and installation of boilers in 1907. Since that time there have followed New York, New Jersey, Pennsylvania, Ohio, Indiana, Michigan, Wisconsin, Minnesota, California, the U. S. Navy and other branches under Government supervision.

From the manufacturers' angle we can readily appreciate that through standardization the small manufacturer would be given the benefit of the years of research and study of some of the brightest engineers in the country, while the large manufacturer would be given the benefit of large-scale standardized construction. The purchaser of boilers, while not conversant with boiler construction, could feel reasonably safe in buying a boiler coming under the A.S.M.E. Code requirements so far as safety is concerned. This does not mean that all boilers would be equally safe. It simply means that for the type of boiler under consideration the purchaser could feel that it was built as safely as that particular construction would allow.

At the present time there are in force quite a number of boiler laws for the different states. It is not unusual to see a boiler stamped as good under Massachusetts boiler laws, the laws of Ohio, or the city of Cincinnati. This brings us fact to face with a very vital necessity, namely, that of *standardizing these laws*.

Unless the states which have not passed boiler laws wake up to their responsibilities, all the old, second-hand boilers from

[1] Sales Engineer, The Babcock & Wilcox Co., Assoc. Mem.Am.Soc.M.E.

Abstract of paper presented at a meeting of the Atlanta Section of The American Society of Mechanical Engineers, October 1918.

their progressive sister states will find a sale in them and will be a source of unending trouble. Boilers do not stand very well being ripped out of their original settings and being reset. Every year the records indicate quite a number of explosions from this very cause alone.

The active work so far done in our state of Georgia was started by Mr. Chas. E. Gorton, Chairman of the American Uniform Boiler Law Society, on a visit in the south this year. He interviewed many of those interested, and as a result State Senator Wohlwender of the 24th district introduced in the state senate a bill covering Mr. Gorton's recommendations. The bill was referred to a Committee on Commerce and Labor.

Inasmuch, however, as this session of the legislature was an adjourned session and there were a large number of bills before the assembly, this bill was never reported out of the committee. The Commissioner of Commerce and Labor was, however, favorable to the bill and it had his entire approval. The text of the bill is given below in the belief that it will prove of value to engineers in other states who are considering the question of boiler standardization:

Senate Bill No. 258, by Mr. Wohlwender of the 24th. Commerce and Labor.

An Act to establish a State Board of Boiler Rules in the State of Georgia; to define the duties and powers of said Board; to pro the use of steam boilers in this state; to provide for the appointment of Boiler Inspectors; to provide penalties for the violation of this Act, and for other purposes.

Be it enacted by the General Assembly of the State of Georgia, and it is hereby enacted by authority for the same:

Section 1. There is hereby created a State Board of Boiler Rules in the State of Georgia, to be known and styled as the Georgia State Board of Boiler Rules.

Section 2. Said board shall consist of three members. The Commissioner of Commerce and Labor of the State of Georgia shall be ex-officio one of such members, and shall be chairman of such board. Within ten days after the passage of this Act it shall be the duty of the Governor of this state to appoint two members of said board. One of said members to be appointed by the Governor shall be a man who shall have been actively engaged in the manufacture of steam boilers in this state for the period of three years prior to his appointment and the other of said members to be appointed by the Governor shall be a man who shall have been actively engaged in a business in this state requiring the use of steam boilers in the operation of said business for a period of three years prior to his appointment. Within ten days after any person shall be notified of his appointment as a member of said board by the Governor he shall accept or decline said appointment and upon his acceptance he shall subscribe and forward to the Governor the following oath: "I do swear that I will faithfully and impartially perform the duties of a member of the Georgia State Board of Boiler Rules to the best of my ability, so help me God." Upon such oath being filed in the office of the Governor he shall issue to said member a certificate of his appointment.

Section 3. From the fund derived from inspection fees provided for in Section 6 of this Act, the members of said Board of Boiler Rules shall be allowed and paid their reasonable traveling expenses incurred in attending to the business of such board. No member of the board shall receive any compensation for his services except the Secretary-Treasurer, who may be paid a reasonable compensation for his services as such, payable from the fund derived from inspection fees as provided for in Section 6 of this Act.

Section 4. The term of office of each member of said board to be appointed by the Governor shall be three years, subject, however, to the following provisions: Of the two first appointments to be made by the Governor to membership on said board one shall be made for the period of two years and one for the period of three years, and after the expiration of the terms of office of the members so first appointed each subsequent appointment shall be for a term of three years, and any vacancy that may occur for any cause shall be filled by the Governor for the unexpired term. The person who may be appointed to any vacancy on said board shall possess the same qualifications for membership on said board as those required by this Act of his predecessor in office.

Section 5. The first meeting of said board shall be held within thirty days after the appointment of the first two members of said board hereinbefore provided to be appointed by the Governor, and at a time and place to be designated by the Commissioner of Commerce and Labor of this state. At its first meeting and annually thereafter said board shall elect from its membership a vice-chairman and a secretary-treasurer ,each of whom shall hold his office until his successor is elected and qualified. The secretary-treasurer shall give a bond in such sum as the board may determine. Said board shall prescribe such rules and regulations for its proceedings and government as will carry into effect the provisions of this Act. There shall be at least two meetings of such board held each year on the second Wednesday in January and July. Special meetings may be held on the call of the chairman of the board. A majority of said board shall constitute a quorum. Said board shall keep a record of its proceedings and a register containing the names and addresses of all persons, firms and corporations to whom permits shall be issued allowing steam boilers to be used or operated in accordance with the provisions of this Act and the rules and regulations prescribed pursuant to the same.

Section 6. The said Georgia State Board of Boiler Rules is hereby charged, directed and empowered:

To formulate and publish rules and regulations for the safe and proper construction and use of steam boilers in connection with manufacturing and industrial enterprises in this state, such rules and regulations to conform as near as may be practicable in the judgment of said board with the Boiler Code of The American Society of Mechanical Engineers.

The rules and regulations formulated and published by said Board of Boiler Rules shall become effective on and after the approval of the same by the Governor of this state. Rules requiring a change in methods of construction of boilers or in the character of materials used shall not be enforced until six months after their approval by the Governor. The provisions of this Act shall not be construed to apply to boilers installed prior to the time when this Act becomes effective, except in so far as the same become necessary, in the judgment of said board, to protect life and property. After any of such rules and regulations so formulated and published by the board and approved by the Governor shall become effective, no steam boiler for use in connection with manufacturing or industrial enterprises shall be installed in this state which does not conform to such rules and regulations.

To employ a Chief Inspector of Boilers and such deputy inspectors of boilers as in the judgment of said board may be necessary, and such office help as in the judgment of said board may be necessary, and to fix the compensation of such inspectors and office help, such compensation to be paid from the fund derived from inspection fees provided for in Section 6 of this Act. Such Chief Inspector shall possess qualifications which shall be prescribed by said Board of Boiler Rules, and each deputy inspector shall be appointed only after he shall have satisfactorily passed in the judgment of said board a written examination as to his fitness for such position, which said examination shall be conducted in accordance with such rules and regulations as may be prescribed by the said board.

To issue and revoke permits allowing boilers to be operated in accordance with the provisions of this Act and the rules and regulations prescribed pursuant to the same.

To keep a complete record of the type, dimensions, age, conditions, pressure allowed upon, location and date of last inspection of all boilers to which this Act applies.

To fix the fees to be paid by the owners and users of boilers to be inspected under the provisions of this Act and the rules and regulations prescribed pursuant to the same, provided that no fee for the inspection of any boiler internally and externally inspected shall exceed the sum of five dollars per inspection, and provided, further, that not more than ten dollars shall be collected for such inspections of any one boiler during any one year.

Section 7. In addition to the inspectors authorized by Section 6 of this Act, the board shall upon the request of any company authorized to insure boilers in this state, issue to any boiler inspectors of said company commissions as special inspectors of the Georgia State Board of Boiler Rules, but such special inspectors shall receive no compensation from, nor shall any of their expenses be paid by, said board, and the continuance of a special inspector's commission shall be conditioned upon his continuing in the employ of a duly authorized boiler inspection and insurance company, and upon his maintenance of the standards imposed by the rules and regulations prescribed pursuant to this Act for the construction and operation of boilers. Such special inspectors shall inspect all boilers insured by their respective companies, and issue permits for the operation of such boilers, copy of which he shall transmit to the Board of Boiler Rules, and such insured boilers shall be exempt from all inspection, other than that of the respective insurance companies' inspectors. Each special inspector shall within ten days following each annual inspection made by him report the date thereof to the Board of Boiler Rules.

Section 8. All fees for inspections of boilers provided for under Section 6 of this act shall be paid in advance to the Secretary-Treasurer of the said board to be held as a fund for the use of said board. No funds shall be paid out except on a warrant signed by the chairman and the secretary-treasurer of said board and no expense of any character shall be created in excess of the amount derived from fees to be fixed in accordance with the provisions of Section 6 of this Act. The funds derived from such fees shall be applied by the board to the compensation of members appointed by the Governor as provided in Section 3 of this Act and to expenses of operation of said board including compensation to be paid inspectors and office help. All surplus on hand on January 1 of each year, after paying all expenses of the operation of said board, shall be turned into the State Treasury.

Section 9. The provisions of this Act shall not apply to boilers in marine or railroad service that are under the inspection regulations of the United States Government, or to motor road vehicles, or to boilers of fire engines brought into the state in an emergency to check conflagration, nor shall it apply to boilers used exclusively for low-pressure steam and hot-water heating and boilers used exclusively for

hot water supply, carrying a maximum allowable working pressure not to exceed 15 pounds per square inch on boilers used exclusively for low-pressure steam heating, and not to exceed 30 pounds per square inch on boilers used exclusively for hot-water heating or hot-water supply.

Section 10. Any person, firm or corporation violating any of the provisions of this Act or any provisions of the rules and regulations prescribed pursuant to the same shall be deemed guilty of a misdemeanor and upon conviction thereof shall be fined not exceeding one hundred dollars or imprisoned for not exceeding three months in the discretion of the court.

Section 11. The rules and regulations to be prescribed by said Board of Boiler Rules pursuant to this Act shall become effective on January 1, 1919.

Section 12. Be it further enacted that all laws and parts of laws in conflict with the provisions of this Act be and the same are hereby repealed.

In conclusion, we find that the only effects that the adoption of the laws would have on the present installations would be to render them safe through the inspection of regular inspectors of the state or insurance companies.

All new boilers would conform to the code as prescribed by this Society.

We can each do our part by getting behind the organizations which we represent and get them to do their part through members of the state legislature. We should each ask ourselves if we are willing to sit still and see this law, which would uplift our state as outlined, tabled again at the next session of our legislature. Practically all the boiler manufacturers represented in Georgia are prepared to build code boilers, and it will take only our concerted efforts to put this bill through next year.

WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in THE JOURNAL, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 200-206, inclusive, as formulated at the meeting of October 25, and approved by the Council. In this report, as previously, the names of inquirers have been omitted

CASE NO. 200

Inquiry: Can the requirements of Par. 312 of the Boiler Code be construed to imply that protecting coverings of non-conducting material may be removable the same as if a cast-iron removable sleeve were used? A literal interpretation of the paragraph as worded would seem to indicate that only a cast-iron protecting sleeve may be removable.

Reply: It was not the intent of the Committee to limit the application of the term "removable" to any particular form of protecting covering, as it is obviously desirable that any form of covering should be easily removable for convenience of examination of the blow-off pipe.

CASE NO. 201

Inquiry: May rivets be used where the heads are not of the form required by Par. 255 of the Boiler Code (Edition of 1918), which refers to specific forms of rivet heads that are acceptable under the rules, but where they are driven with forming tools which bring the final form to any one of the acceptable forms of heads shown in Fig. 20?

Reply: The requirements of Par. 255 may be considered as fully met if the form and proportions of the finished heads correspond to those indicated in Fig. 20 of the Boiler Code (Edition of 1918).

CASE NO. 202

Inquiry: What is the correct method under the rules of the Boiler Code (Edition of 1918) of calculating the safety valve requirements for waste-heat boilers used in connection with the manufacture of illuminating gas, to which the boilers are driven alternately during the blow periods of water-gas machines, and in which there are occasions when the tarry deposit from the gas must be burned off the heating surfaces, producing a temporary extremely high rate of local heating?

Reply: The minimum number and size of safety valves required for these boilers as in other boilers, is determined by Par. 271. In this case the Committee considers this safety valve capacity should be checked by Par. 275*a*, and if found insufficient should be increased.

CASE NO. 203

Inquiry: Will an automatic fire door which consists of a metal plate or plates that slide within retaining guides or grooves, meet the requirements of Par. 328 of the Boiler Code in which specific reference is made only to doors of the inward-opening type or those which are provided with a substantial and effective latching device? A sliding door of the type above described, obviously is neither of the inward-opening type nor has it any latching or fastening devices.

Reply: The intent of the requirements in Par. 328 was that means shall be provided to prevent the firing or inspection door "from being blown open by pressure on the furnace side," and the ruling is therefore not limited to the specific types of mechanisms named. If a door is so constructed that it cannot be blown open by pressure on the furnace side, no matter in what position it may be found, it obviously meets the requirements of Par. 328.

CASE NO. 204

Inquiry: An interpretation is requested of what may be considered a "substantial and effective latching or fastening device" for firing or inspection doors to prevent them from being blown open by pressure on the furnace side. Does an over-balanced weighted form of latch which is so fitted to the fire door fulerum that it cannot jump out of latch when the door is closed under any conditions, meet the requirements of this rule?

Reply: The intent of the requirement in Par. 328 was that means shall be provided to prevent the firing or inspection doors "from being blown open by pressure on the furnace side." If a door is so constructed that it cannot be blown open by pressure on the furnace side, it obviously meets the requirements of Par. 328.

CASE NO. 205

(In the hands of the Committee.)

CASE NO. 206

Inquiry: Is it permissible, in bracing the rear lower segment of an h.r.t. boiler, to so design the angle irons of the structural reinforcement used across the rear head for attaching through braces, that they may also be considered as taking the place of a certain amount of through stay area.

Reply: The practice referred to in the inquiry is permissible if the members are designed in accordance with the requirements for structural reinforcements in Par. 201 of the Boiler Code (Edition of 1918).

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, Including Abstracts of Articles in Current Technical Periodicals

Boring for Oil in Britain

WHAT may be called the inauguration of the crude-oil industry in the United Kingdom took place in October. A public ceremony on the Duke of Devonshire's estate, about seven miles south of Chesterfield, marked the beginning of the first boring operation.

American aid is figuring prominently in the situation. Not only has most of the machinery to be used been imported from the United States, but forty drillers have been brought over and will work under the supervision of one of the foremost oil experts of America.

The scheme originated in the enterprise of Lord Cowdray, head of the firm of S. Pearson & Son, Ltd., who has placed at the disposal of the British government the services of the firm's geological experts and the information which they have accumulated. The firm is now directing the work as agents of the Ministry of Munitions.

What has been done is all preparatory work. It throws no additional light on the probabilities of oil being found. The boring of the wells, a long and expensive process, is the only decisive test. But Lord Cowdray and those with him have great confidence in the accuracy of the conclusions which the experts have made. These conclusions are based on a study of the geological formation of the district, and they have not been hastily drawn. Investigations were begun in 1914 under the direction of Dr. Veatch, an American petroleum expert, who was formerly connected with the United States Geological Survey.

A considerable time must elapse before the success or failure of this first well can be determined. (*Journal of Commerce*, Nov. 1, 1918, p. 2)

Output of New Locomotives Doubled in Three Months

B. M. Baruch, Chairman of the War Industries Board, authorizes the following:

The standard-gage steam-locomotive industry of the United States, operating under the direction of the War Industries Board, has increased its rate of production approximately 100 per cent in the past three months. Last week the output of the three standard-gage companies was 144 locomotives. Since 1910 and up to last August, the highest number ever turned out in a single year was 3776, which would prove an average weekly output of 72.6 locomotives.

The achievement is particularly noteworthy from the fact that, in bringing about the tremendous jump in production, it has been unnecessary to expend a dollar to increase plant facilities or enlarge the existing works, items of considerable expense in the development of most of the other war industries of the country. Redistribution of orders and concentration by each of the plants on particular types of locomotives has made possible the intensity of effort unprecedented in the industry.

The "Pershing" locomotive, built on standardized plans designed by the United States Military Railways, has not only been made the sole type of steam locomotive in use behind the American lines in France, but, at the instance of the War Industries Board, has been adopted by the British and French governments as the standard type for their armies on the western front.

Last August the Government, face to face with an immediate and urgent demand for steam locomotives for use in this country and France, was seriously considering the establishment of Government plants to meet the emergency. It was proposed that approximately $25,000,000 should be spent for this purpose. At the suggestion of the War Industries Board the expenditure was held up in favor of the present plan.

Under the arrangement adopted, the construction of all the locomotives of standard gage for use in France was assigned to the Baldwin Locomotive Works, whereas all orders for the United States Railroad Administration were divided between the American Locomotive Co. and the Lima Locomotive Works. These three companies comprise the entire standard-gage steam-locomotive industry of the country. By this method of distributing the work, each of the plants has been able to develop extraordinary speed.

Normally the output of the Baldwin Works never exceeded 60 locomotives a week. Last week it turned out 87 engines complete, not to mention 7 gasoline locomotives and 3 electric locomotives, and general repairs on ten steam engines, and the promise is for even better returns during the present month. The American Locomotive Works has likewise accomplished excellent results, for while the number of locomotives is not so great, the tonnage represented in the output is proportionately as large; that is to say, whereas the "Pershing" locomotive weighs about 83 tons complete, the average weight of the locomotives called for by the Railroad Administration is approximately 150 tons. Similarly the Lima Works have developed to a marked degree in the last three months; and, as in the case of the other two concerns, without e pansion of plant or plant facilities.

The importance of the results attained in this direction in their relation to the war program generally is indicated by the fact that the Government is spending this year in the construction of these locomotives, both for use in France and on the Government-operated roads in this country, approximately $200,000,000. (*Official Bulletin*, Nov. 2, 1918, p. 1)

British Machine Tools

A British author, J. Judson, recently delivered an address in England containing some rather startling statements. According to this speaker, the British tool industry had been practically stationary during the last quarter of a century before the war, while Germany and America made big strides ahead.

As an illustration, he stated that from 70 to 80 per cent of the machinery used in the manufacture of British aircraft engines is of foreign make. The largest machine tools to be found in Great Britain at the present time (purchased before the war, of course) are of German make.

During 1917 the output of German machine tools was about $200,000,000, while the British output is estimated at only one-quarter of that amount. This tremendous output of German machine tools was necessary to keep up with the demand for munitions of war. Because of the British blockade on the seas the Germans were unable to draw machine tools from America as the British did, and were obliged to make everything for themselves in this particular line. As a result, a very important group of machine-tool makers may appear in the field after the war. (*The Iron Age*, vol. 102, no. 20, November 14, 1918, p. 1199)

Fuel-Oil Conservation Meeting at Chicago

A meeting was held on October 24, which was attended by about 300 representatives from fuel-oil and coal-burning plants in the Illinois district, assembled at the request of Nelson G. Phelps, District Engineer of the Bureau of Oil Conservation. The primary object of the meeting was how to arouse interest in the conservation of oil, to point out wasteful practices and to indicate where improvements might be made. Four technical papers relating to fuel-oil systems were presented.

Max Sklovsky gave information on the use of fuel oil in industrial furnaces and the results of experiments obtained over a period of years by the Deere Company, of Moline, Ill. He stated that improvements in efficiency had been secured by preheating the air of combustion by the waste gases from the furnace to a temperature approximating 700 deg. fahr. The oil was injected

into this air in a mixing receptacle, vaporized and thoroughly mixed with the proper proportion of air and was delivered to the furnace in gaseous form. The furnace should be airtight. A comparison between the old straight-type furnace and the new furnace burning the oil in the form of gas and preheating with waste heat, showed that the oil consumption was reduced to practically one-third of the quantity formerly required.

J. J. Connelly, in a paper entitled Oil Storage and Measurement, made practical suggestions in reference to storage tanks, pipe lines to the furnaces, and meters to measure the oil used. He emphasized the necessity of having some method of measuring the oil consumption, and called attention to the fact that by no means had all the plants provision for measuring the oil consumed or for determining what economy was being obtained.

Fuel-Oil Combustion in Industrial Furnaces was the title of a paper by Joseph W. Hays, Mem.Am.Soc.M.E. He compared fuel-oil firing with coal burning, enumerated in a general way the conditions required for efficient combustion, and made a strong plea for the use of CO_2 recorders. (Abstracted through *Power*, vol. 48, no. 19, November 5, 1918, pp. 684-685)

American Institute of Electrical Engineers

A meeting of the Institute was held in New York on November 8, 1918.

A paper was presented by R. B. Williamson, C. A. Kelsey, A. M. Dudley and H. Veichsel, acting as a sub-committee of the Industrial and Domestic Power Committee, appointed to compile a typical survey of the application of electric motors to a representative industry, standardizing methods for the selection of motors. This survey is expected to serve as a model for the survey of this phase of other industries.

The paper begins by giving a brief description of the process of manufacturing cement, which is followed by an outline of the various kinds of machinery used, together with data as to power requirements. From this outline it appears that the grinding of the clinker into finished cement requires more power than any other step in the process, as the clinker is, as a rule, much harder to grind than the raw materials. Further, there is at present a tendency to demand more finely ground cement, specifications for portland cement in the United States having been changed in 1916 from 75 per cent through 200 mesh to 78 per cent through 200 mesh. There is also a greater tendency to grind the raw material extremely fine, and it is claimed that the extremely fine grinding of raw materials has the advantages that fuel is saved, a better cement is produced, and the clinker is more easily ground.

As regards motors, it is stated that alternating-current motors are preferable for cement-mill operation. There are two main reasons for this: (1) A relatively higher voltage can be used—from 440 or 550 volts up to 2200 volts for some of the motors in large mills; and (2) the greater mechanical simplicity of the a. c. motor, particularly that of the squirrel-cage type. There are, however, a number of mills equipped with d. c. motors which give excellent service.

A number of recommendations are given for guidance in selecting motors for a cement mill. Among these are the following: Starting conditions are quite severe and make phase-wound rotor motors preferable or even essential; bearings should be made dustproof, as cement has a highly abrasive action; it is good practice to supply outboard bearings for belted motors of 75 hp. and larger; pulleys larger than usual in both diameter and length are often specified, since the cement dust causes more than normal belt slippage and makes necessary tighter belts and increased strain on bearings.

As regards the type of motor, it is stated that while the induction motor has been used almost exclusively in the past, there are indications that synchronous motors will be adapted to this work more in the future. This is especially so in the case of low-speed motors for geared tube mills.

The load factor of the average complete cement plant runs from 65 to 75 per cent taken through the entire year, and is probably the highest of any industry. It may be as high as 95 per cent, since the machines run at all times under constant full load.

An interesting description and discussion of the various types of crushers, crushing rolls, rotary driers and grinding machinery is presented, making the paper of considerable interest not only to electrical but also mechanical engineers.

The complete paper is published in the Proceedings of the American Institute of Electrical Engineers, vol. 37, no. 11, November 1918, pp. 1237-1273. The discussion has not yet been published.

Society of Naval Architects and Marine Engineers

The 26th annual meeting of the society was held in Philadelphia, Pa., on Thursday and Friday, November 14 and 15, 1918. Excursions were arranged to various shipyards on the Delaware River, and the following papers of special interest to mechanical engineers were presented:

Application of Buoyancy Boxes to S. S. *Lucia* for the U. S. Shipping Board, W. T. Donnelly, Mem.Am.Soc.M.E.

On Vibrations of Beams of Variable Cross-Section, N. W. Akimoff, Mem.Am.Soc.M.E.

Experiments Upon Simplified Forms of Ships, Prof. H. C. Sadler and T. Yamamato

Variation of Shaft Horsepower, Propeller Revolutions and Propulsive Coefficient with Longitudinal Position of the Parallel Middle Body in a Single-Screw Cargo Ship, Commander Wm. McEntee

The Application of Electric Welding to Ship Construction, H. Jasper Cox.

Abstracts of these papers will probably be published in an early issue of THE JOURNAL.

Society of Automotive Engineers

At a meeting of the Mid-West Section of the Society of Automotive Engineers, in Chicago, November 8, P. J. Dasey presented a paper on Lubrication and Fuel Tests on the Buda Tractor-Type Engines.

In this paper a statement was made that there would probably be commercially available in a short time a new fuel, a reworked petroleum product, which would cost much less than gasoline, but which, except for ease of starting and for extremely high-speed engines, is claimed to have as good power and fuel-economy characteristics as gasoline.

This product Dasey calls "synthetic crude," and his paper was devoted chiefly to reports of careful tests in the Buda laboratories of this fuel in comparison with four other fuels, namely, gasoline, cracked benzine, cracked gasoline and kerosene. These tests were made on the new Buda tractor engine model HTU, using a standard Stromberg carburetor.

Summarizing the tests on these fuels and averaging the results of five runs on each fuel for power and economy at different speeds, he found the following in brake horsepower-hours per gallon:

Commercial gasoline	7.80
Cracked gasoline	7.92
Synthetic crude	8.02
Cracked benzine	8.23

(*Motor World*, vol. 57, no. 7, November 13, 1918, p. 33)

Child Labor Increasing

Investigations recently conducted by the Children's Bureau of the Department of Labor show that there has been a great increase in child employment since the Federal child-labor law was declared unconstitutional last June. In twenty-four states, including Pennsylvania, the southern textile states and New England, except Massachusetts and Vermont, the reports indicate there has been a general return to the nine-, ten- and eleven-hour day for children under sixteen years of age. In these states the eight-hour day is not required by statute for children between fourteen and sixteen years of age. Philadelphia *Public Ledger*, Nov. 6, 1918, p. 10)

Aeronautics

Battle Acrobacy or Trick Flying, Capt. K. G. Pulliam, Jr., U. S. A. Description of the various forms of "stunt" flying written by the authority of Air Service Headquarters, A. E. F.

The object of training fighting pilots in stunt flying is to teach them how to meet dangerous conditions of flight which they may encounter (Gosport system of training).

At a field where trick flying is taught every student is given individual attention and instruction. Only one stunt at a time is explained and unless every movement is thoroughly understood by the student he is not permitted to attempt the work.

The Vrille. This is one of the most disconcerting of all stunts and is the first to be taught. In starting the pilot ascends to at least 1200 meters and after flying level for several minutes throttles his motor and just at the point where the machine stalls he pulls the control stick quickly back toward him and at the same time to the side, accompanying it by a sudden push of the rudder bar, using the foot corresponding to the side on which the stick is placed.

As a result the machine shoots suddenly up, losing speed, and falls sharply over to the side with a twisting corkscrew-like movement. In every case the twist commences sharply and the student is instructed to place his controls in neutral after the machine has made several turns and to *slowly* push the control stick forward a few inches. The machine ceases to whirl, points forward and dives straight down, the pilot at once redressing his control stick and bringing his machine again into horizontal flight, at the same time switching on the motor.

The Renversement. Although the use of this stunt in actual combat is questionable the student should be familiar with it, as any pilot who can manage it will be able to control his machine whether or not he is in an upside-down position.

To perform the renversement the pilot ascends to the height of 1200 meters, flies for a few minutes, then points the machine *very* slightly downward so as to bring the speed up to maximum, pulls the control stick back sufficient to raise the nose of the machine to an angle of 20 or 30 deg. If a left-hand renversement is desired the rudder should be pushed hard to the left. As a result of the above control motions the nose of the machine jerks sharply upward, followed by a roll of the entire machine to the left. Just before the machine is completely on its back the motor is cut and the pilot places his controls in neutral; the plane stops its roll and the pilot pulls back on the control stick, causing the machine to dive and almost at once resume the horizontal, at which time the motor is switched on, the stick placed in neutral and normal flight resumed.

Since the pupil when flying in the head-down position in which he hangs when the machine is on its back, is not likely to recognize the moment at which the controls should be placed in neutral, he is instructed to immediately neutralize the rudder after he has thrust the control to the left.

The Immelman Turn. This stunt was first used in combat by Lieutenant Immelman of the German Flying Corps. To perform the Immelman turn the pilot again ascends to the height of 1200 meters and after flying level for a few minutes he points the nose of the machine down very slightly and then pulls slowly back the control stick, causing the machine to climb almost vertically. Care should be taken not to pull enough on the stick to cause the plane to loop. The motor should be cut as soon as the machine starts to climb and as soon as excessive loss of speed is felt the rudder is pushed sharply to one side. The machine falls to the side on which the rudder is pushed and as soon as the machine reaches vertical the pilot places the rudder in neutral, switches on the motor and by pulling back on the stick resumes normal flight. A slight movement of the stick to the side corresponding to the rudder used will help the movement.

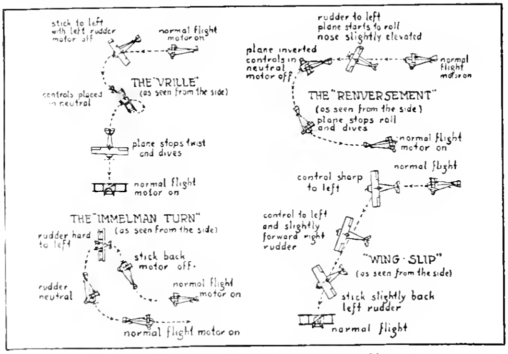

Fig. 1 Various Forms of Stunt Flying

When done properly the turn is a very pretty performance and no loss of altitude results. It can be performed to either side with uniform results, and after the pilot is thoroughly accustomed to the movement he may use his motor throughout the complete evolution with no loss of speed.

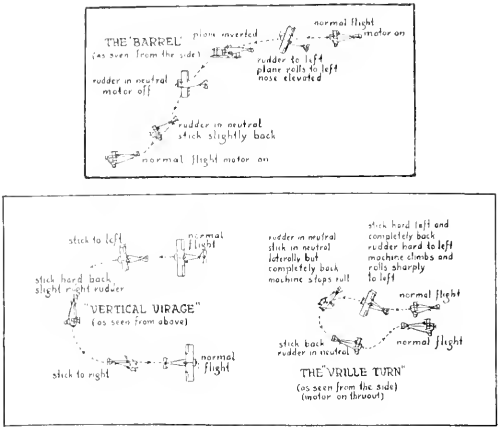
The Barrel. The "barrel" might also be called a horizontal vrille and it is performed exactly the same as the renversement, with the exception that the controls are not placed in neutral when the machine is upside-down, just before the machine again reaches normal line of flight. The first movements of the machine are identically the same as when in a renversement, but the roll continues until the plane has made one roll of 360 deg., at which time the motor is switched on and normal flight resumed.

The Vertical Virage. The vertical virage is nothing more or less than a turn in which the plane is banked until the wings are perpendicular to the ground and elevators are used for turning. It is used to turn quickly into the opposite direction without loss of either speed or altitude.

Flying level at full speed the necessity to turn suddenly is met by throwing the control stick to the side on which the turn is desired and accompanying it with a little corresponding rudder. When the position is reached in which the wings are perpendicular to the ground the stick should be placed in neutral and pulled hard back. The movement should be accompanied by opposite rudder sufficient to keep the nose of the machine from falling.

As a result of the above movements the machine banks sharply and as the stick is pulled back it seems to spin around, using the tip of the low wing as a pivot. As soon as the desired amount of turn has been made the pilot places his stick to the opposite side from which the machine is banked and the plane levels out and resumes normal flight.

The Side-Slip. Since the side-slip allows the pilot to lose an abnormal amount of altitude in proportion to the distance progressed forward, it is a very useful stunt. A pilot in making a forced landing may allow himself to overshoot his landing field and then side-slip off any surplus altitude, thus assuring his reaching the field.



Figs. 2 and 3 Various Forms of Stunt Flying

In aerial combat and in dodging anti-aircraft fire it is also very useful, as it is a method of losing altitude very rapidly, and since in a side-slip the direction of motion is not directly forward it is very disconcerting to an enemy firing at the machine.

A side-slip is accomplished by pushing the control stick all the way to one side and accompanying it by sufficient pressure of the opposite foot to hold the nose of the machine up. The control stick is at the same time pushed slightly forward and the machine descends sidewise at a terrific speed.

To recover from a side-slip the control stick is placed in neutral and the rudder corresponding to the direction of the slip is pushed. As a result the machine turns and dives into the direction of the slip and by redressing the stick straight-away flight is resumed.

The Vrille Turn. The vrille turn is very similar to the renversement, but, unlike the latter, it is very useful in air combat. It is performed with full motor and is a very rapid evolution.

The stick is pulled quickly all the way back and completely to the side, accompanied by a sharp kick of the rudder to the left. As a result the nose of the machine jerks up and the plane rolls to the left.

The rudder is immediately placed in neutral and the stick is brought back to the center but held completely redressed. The neutralizing of the rudder stops the roll and as the stick is held completely redressed the nose of the machine immediately climbs to level and normal flight is resumed. No loss of altitude results.

As the motor is used throughout the turn the motions are necessarily very rapid and rather disconcerting when first attempted, but one soon becomes accustomed to the rapidity of the twist.

The Loop. The loop is accomplished by putting the nose of the machine down slightly to obtain maximum speed and then pulling back on the control stick, slowly at first and more rapidly as the top of the loop is reached. Just after the top has been passed the motor should be cut, the machine being allowed to fall of its own momentum through the last half. When the loop is completed the stick should be placed in neutral, the motor switched on and normal flight resumed. When looping with a plane using a rotary motor some left rudder should be used at the top of the loop to prevent falling out of the loop to the right.

A loop improperly done may result in a vrille, and taken as a whole looping is of no value in a fight, for while a machine is inverted the pilot is quite helpless until the machine has passed the "dead point" and started downward, thus giving an enemy who is following a good target. The machine-gun belt is likely to become disarranged and cause the gun to jam.

If the loop is improperly done the reversals of pressure are very severe and are extremely hard on a finely adjusted and very fast machine, but a loop properly done causes very little strain.

The Tail-Slide. A real tail-slide should not be accomplished with a machine using either ailerons or wing flaps for lateral control, because when it is properly done the reversal of pressure may cause them to buckle.

A tail-slide should never be attempted by even the most experienced pilot unless he has an especially built exhibition plane, preferably a monoplane, which is equipped with warping wings and is constructed strong enough to withstand the tremendous reversal of pressure.

A stall accompanied by a slight drop of the tail, followed by a slipping off to the side into a vrille, cannot be called a tail-slide, for a well-performed tail-slide will extend for at least 300 meters.

The Time and Place for Acrobacy. Acrobacy at low altitudes is strictly forbidden at training schools and it should never be done close to the earth except in cases of emergency and actual combat.

A pilot cannot at all times be sure of the condition of the atmosphere which he cannot see and fatal falls often result when overconfidence meets with bad air conditions near the ground. (*Aerial Age Weekly*, vol. 8, no. 8, November 4, 1918, pp. 422-423, 3 figs., *d.*)

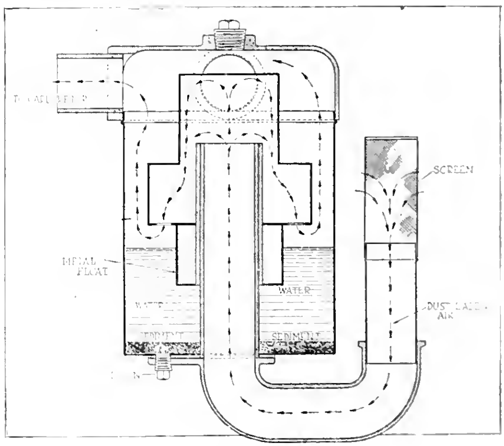


Fig. 4 Liquid Air Cleaner

Air Machinery

Air Cleaners, W. G. Clark. Analysis and comparison of various air cleaners such as used for washing the air on tractor engines.

The writer divides all cleaners now in use on tractors and trucks into four types: (1) cloth or screen type; (2) inertia cleaners; (3) liquid-type cleaners where water or some other liquid is used to wash the air, and (4) centrifugal or gravity

cleaners. The various types are briefly described and illustrated.

The disadvantage of the cloth- or screen-type cleaners lies in their being difficult to handle, ineffective and bulky. They must be very large in order to cut down the air velocity. The cloth or screen soon clogs and restricts the flow of air to the carburetor.

The action of inertia cleaners depends on the inertia of the dust in the air to carry it out of the air stream when the air flow is suddenly reversed or changed before passing to the carburetor.

The third type comprises those cleaners in which the liquid is employed to trap the dust. One such cleaner is shown in Fig. 4. It is said that this cleaner has the objection of employing a floating member with a large bearing surface exposed to the wearing action of the dust entering the cleaner.

Several types of centrifugal cleaners are described and illustrated.

The writer claims that the efficiency of the liquid and gravity types is approximately the same, but that the former may have an advantage in that the water entering by the air aids in the process of carburetion. (Paper presented at a recent meeting of the Minneapolis Section of the Society of Automotive Engineers, abstracted through *Automotive Industries*, vol. 39, no. 16, October 17, 1918, pp. 678-680 and 696, 8 figs., *cd*)

Fuel and Firing

Fuel Tests in Northern Saskatchewan. A series of tests was conducted at the Prince Albert Power Plant, Alberta, Saskatchewan, to determine the relative values of various fuels available locally.

The fuels tested were bituminous and lignite coals from the Province of Alberta, jack pine and poplar cordwood, spruce edgings, planing-mill shavings and hog fuel. The tests were carried out on a hand-fired 72-in. return tubular boiler 18 ft. long, normal rating 150 hp. The grates used were one-half herringbone pattern, having a total grate area of 36 sq. ft., with air spaces forming approximately 45 per cent of the total area.

TABLE 1. RESULTS OF TESTS WITH SASKATCHEWAN FUELS

	Bituminous Slack	Lignite 50 Per cent Nut 50 Per cent Slack	Jack Pine Cordwood	Poplar Cordwood	Spruce Edgings
Duration of test, hr....	6	6	6	6	6
Gage pressure, lb.........	125	125	125	125	125
Average temperature feedwater, deg. fahr..........	177	179	180	180	178
Average temperature flue gases, deg. fahr...................	490	495	500	485	490
Thickness of fire, in......	9	4	24	24	24
Draft, in.................	0.12 to 0.19	0.04 to 0.27	0.01 to 0.02		0.00 to 0.01
Total water evaporation, lb...	24,200	22,800	23,600	24,000	24,400
Total fuel fired, lb.......	2,600	4,100	5,565	6,830	8,022
Total fuel fired, cords of 128 cu. ft.			2.1	2.75	3.6
Total weight ash and clinker, lb.....	314	371	37	57	108
Per cent ash and clinker.	12	9	0.65	0.85	1.35
Water evap. per lb. of fuel as fired, lb.	9.3	5.6	4.3	3.5	3.0
Equivalent evaporation from and at 212 deg. fahr. per lb. of fuel	10.0	6.0	4.6	3.8	3.3
Equivalent evaporation from and at 212 deg. fahr. per cord of 128 cu. ft.			12,100	9,400	7,300

In tests with some of the lignites the fires were not cleaned, the boiler operating, roughly, not higher than at 80 per cent of its rated capacity. With other fuels the fires were cleaned about every two and a half hours. A fuel bed about 4 in. in thickness was found most suitable, and the best results were obtained when the clinker was left undisturbed; no slice bar being used. In fact, the use of the bar seemed to increase the amount of clinker even when the greatest care was exercised. This applies apparently especially to the case of burning lignite slag.

In the tests with wood the same herringbone grates were used as for coal, but the ends next to the bridge wall for a distance of 18 in. were covered with sheet iron protected by a layer of ashes. A poker was used occasionally to consolidate the fuel, and the furnace was kept as full as possible.

The quantity of ash with wood was very low, and the grates did not require any cleaning at all. It is stated that the firemen experienced in handling cordwood claimed it much easier work than firing coal. The results of the tests are given in Table 1. (*Power*, vol. 48, no. 18, October 29, 1918, pp. 624-625, *e*)

Heating and Ventilation

A Ventilation Paradox, Thos. R. Wilson. Description of air conditions in the Chicago freight tunnel.

The enormous quantities of various materials through which the tunnel is driven (including water) act as a great reservoir of heat, extracting heat from the tunnel air when the latter is warmer than the tunnel surface. During cold weather the opposite flow of heat takes place, the heat stored in the materials about the tunnel being given back to the air through the millions of square feet of tunnel surface. These conditions balance so accurately that the entire temperature variation throughout the year in the tunnel air is less than 10 deg.

This had a rather unusual result. In the summer months air is almost always in a saturated condition as the outside air is cooled to the dewpoint. This keeps the tunnel air practically free from dust, partly because the condensation of moisture on the dust particles causes their precipitation to the tunnel invert.

In the summer of 1916 a complaint was received respecting the use of tunnel air in a cold-meat storage room of a certain downtown hotel, the claim being made that such air is unsanitary. Various tests for air purity were made and revealed a remarkable freedom of the air from dust. (*Heating and Ventilating Magazine*, vol. 15, no. 10, October 1918, pp. 42 to 45, 4 figs., *d*)

Hydraulics

Hydraulic Tests of a 715-Hp. High-Speed Water Turbine of Swiss Construction, W. Schmid. Description of tests of a turbine built by Escher, Wyss & Company, of Zurich, Switzerland, and tested in 1917, after installation in the new hydroelectric plant at Thun.

The general construction of the turbine and its installation are apparent from Figs. 5 and 6. The tests were based on the following guarantees of the contract: Net hydraulic head $H = 5$ to 6.1 m. (16.4 to 20 ft.); water discharge $Q = 10{,}300$ to 11,000 l. per sec. (2720 to 2905 gal. per sec.); output N_e is 545 to 715 hp.; speed n 150 r.p.m.; efficiency η at 715 hp. 79 per cent, at 625 hp. 80 per cent, at 535 hp. 77 per cent, and at 447 hp. 73 per cent, with a tolerance of 2 per cent either way. The greatest permissible rise in speed over the respective speeds in the case of sudden removal of load was specified as 3, 6 and 15 per cent, respectively, for loads of 178.7, 357.5 and 715 hp. These contract values correspond to a specific speed of rotation of

$$n_s = \frac{n}{H}\sqrt{\frac{N}{\sqrt{H}}} = \frac{150}{6.1}\sqrt{\frac{715}{\sqrt{6.1}}} = 418$$

As regards the construction of the turbine, Fig. 6 is of particular interest as it indicates the new form of rotor with its large space between the Fink regulating buckets and the rotor buckets proper.

The ventilating pipes open into this intervening space and remain open during operation of the turbine (and also were kept open during the test runs described in the present article), the access of internal air being also allowed freely. This arrangement has been patented and is designed to improve the efficiency at partial load.

The oil-pressure governor of the type generally used by the company is installed here.

The actual tests were carried out on December 9, 1917, and only certain test points in the efficiency curve of the turbine were selected to be established: namely, a point near the peak of the output of the turbine, and about 447 hp.

At the beginning of the first continuous run it was found that

with the turbine under full load it was difficult to maintain constant conditions in the water flow and the gate was reduced to 90 per cent. Thereafter, five tests were carried out in the following order:

1 A two-and-a-quarter-hour run with the turbine gate open 90 per cent for the purpose of determining the efficiency of the turbine.
2 Run with the gate open 100 per cent to determine the maximum output of the turbine.
3 Load on the generator changed from full-load to no-load to determine the rise in potential.
4 A two-hour run with the turbine gate open 72 per cent to determine the efficiency of the turbine at that position.

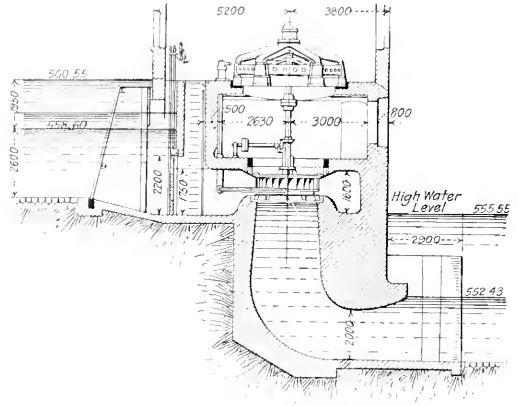

Fig. 5 Section through the New Engine Room of the Hydro-Electric Plant at Thun (scale 1 to 200)

5 Test of the governor control, consisting of observation of increase in speed with change of load on the generator and turbine from full load to no-load.

Efficiency of the Turbine

In Fig. 7 curve A indicates the efficiency of the turbine as a function of the output, on the basis of the guarantees of the builder of the turbine. The two points indicated by the present tests and indicated in that figure have been found by the following calculations:

For an opening of the turbine gate of 90 per cent, the volume of water Q delivered to the turbine was 10.113 cu. m. (357.02 cu. ft.) per sec. and the average actual head 6.067 m. (19.903 ft.). Hence, the available output was

$$N_a = \frac{Q.H.\gamma}{75} = 818.07 \text{ hp.}$$

On the other hand, the output measured at the generator with instruments of high precision and a water rheostat was

$$N = 463.6 \text{ kw.} = 629.89 \text{ hp.}$$

Hence, the overall efficiency of the turbine and generator was

$$\eta_{tot} = \frac{629.89}{818.07}\,100 = 76.997 \sim 77 \text{ per cent}$$

But from an efficiency curve of the generator reproduced in the original article, it appears that at a total output of 463.6 kw. it has a total efficiency of 92.5 per cent, which shows that the efficiency of the turbine alone is

$$\eta_T = \frac{77}{0.925} = 83.24 \text{ per cent}$$

and the output of the turbine

$$N_e = \frac{629.89}{0.925} = 680.96 \text{ hp.}$$

With a gate opening of 72 per cent, the volume of water discharged by the turbine was Q = 6.981 cu. m. (246.48 cu. ft.) per sec. and the actual average head 6.195 m. (20.324 ft.) which gave an available output of power of $N_a = 576.63$ hp. The power output measured at the generator was $N = 304.15$ kw. = 413.25 hp., which gave an overall efficiency of

$$\eta_{tot} = \frac{413.25}{576.63}\,100 = 71.66 \text{ per cent}$$

At that output the efficiency of the generator was found to be 90 per cent, which indicates an efficiency for the turbine alone of

$$\eta_T = \frac{71.66}{0.902} = 79.45 \text{ per cent}$$

and shows that the output of the turbine was

$$N_e = \frac{413.25}{0.902} = 458.15 \text{ hp.}$$

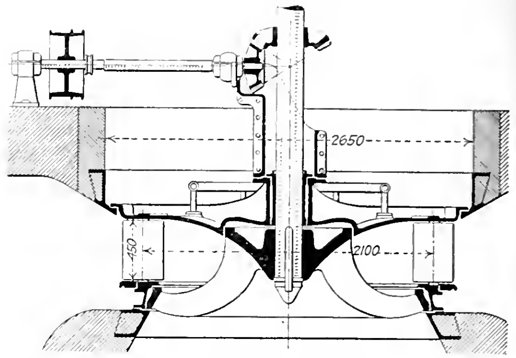

Fig. 6 Section through the High-Speed 715-Hp. Swiss Water Turbine (scale 1 to 40)

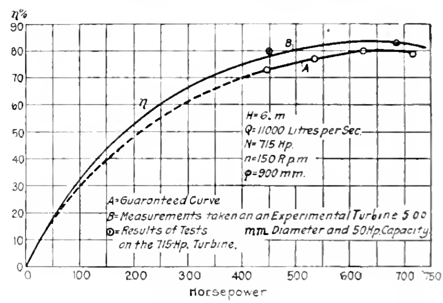

Fig. 7 Efficiency Curves of the High-Speed Turbine shown in Fig. 6

While these two points do not in themselves completely determine the efficiency curve of the turbine, they permit plotting it with a fair degree of approximation when the data of similar tests on other apparatus are taken into consideration. In particular, since the two control points determined by actual tests lie considerably above the guarantee curve, it is reasonable to assume that the entire performance curve is above the guarantee curve.

The values thus found are in fairly good accord with the curve B in Fig. 7, which expresses the conditions in the turbine under test. It is also stated that the measurements were sufficiently precise for all practical purposes.

Maximum Output of the Turbine

In test 2 with the turbine gate wide open the output as measured by the generator was found to be N = 495.9 kw. At this output the efficiency of the generator is 0.926 and the total output of the turbine is

$$N_{e\ max} = \frac{495.9}{0.736 \times 0.926} = 727.6 \text{ hp.}$$

However, during this test the head was only H = 6.014 m. (19.730

ft.), and was, therefore, less than the head specified by the builders of the turbine, or $H = 6.10$ m. (20.003 ft.). When the head varies slightly while the opening of the gate remains the same, the output of the turbine varies in accordance with

$$N_1 = N_0 \cdot \sqrt{\left(\frac{H_1}{H_0}\right)^3}$$

so that with the normal head $H_1 = 6.1$ m. (20.003 ft.) the maximum output would have been

$$N_1 = 727.6 \cdot \sqrt{\left(\frac{6.100}{6.014}\right)^3} = 743.3 \text{ hp.}$$

As a matter of fact, the guaranteed output was $N_e = 715$ hp. at a head of 6.1 m. (20.003 ft.) and an efficiency of 79 per cent, so that the actual performance was about 4 per cent better than the guaranteed performance.

During the test with the gate open 90 per cent, it was found that at maximum output the efficiency of the turbine is about 3 per cent higher than the guaranteed value, and from Fig. 7 it appears that at maximum output the efficiency is around 82.2 per cent. Hence, even if the turbine should take only as much water as was provided for in the designs of the builders, its maximum output would have been still around 743.9 hp., and the agreement of this value with the one calculated above shows the precision of the test with the 90 per cent gate.

To the maximum output corresponds a specific speed of

$$n_s = \frac{n}{H} \cdot \sqrt{\frac{N_{max}}{\sqrt{H}}} = \frac{150}{6.1} \cdot \sqrt{\frac{743}{\sqrt{6.1}}} \sim 427$$

CAPACITY FOR GOVERNING

When the load was suddenly thrown off and thus reduced from 480.1 kw. or 705 hp. to zero, the periodicity, as indicated from the frequency meter, changed from 50 to 56 cycles. Considering that within 10 sec. a constant state of 52 cycles was reached, this indicates a rise of

$$\frac{56 - 52}{52} \times 100 = 7.69\% \sim 8 \text{ per cent}$$

This amount is only a little in excess of one-half of the guaranteed maximum of 15 per cent.

These tests show how closely a large Francis-type turbine of modern construction can hold within guaranteed limits. The speed of 427 r.p.m. is to be considered as being very high, but is of advantage as it reduces materially the first cost of the plant. Also, notwithstanding this high speed, the efficiency of 79.45 per cent at five-eighths load is also very good and indicates that this new type permits utilizing very well the available water heads, even at partial load.

It is true that with the new type the efficiency on loads under half of the maximum decreases more rapidly than with the former standard types. This, however, is claimed to be compensated for by advantages in other directions. (*Schweizerische Bauzeitung*, vol. 72, no. 14, October 5, 1918, pp. 129-131, 4 figs., *eA*)

A PROPOSED HYDRAULIC EXPERIMENT, Lord Rayleigh. Stokes showed in 1850 that in the case of a homogeneous incompressible fluid whenever $udx + vdy + wdz$ is an exact differential, not only are the ordinary equations of fluid motion satisfied but the equations obtained when friction is taken into account are satisfied likewise. It is only the equations of condition which belong to the boundaries of the fluid that are violated.

In order to satisfy these conditions also it is only necessary to suppose that every part of the solid boundaries is made to move with the velocity which the fluid would there assume in irrotational motion.

The only way, however, to carry this into effect with tolerable completeness is by the two-dimensional motion of fluid between co-axial cylinders, which themselves are rotating in the same direction with the circumferential velocities which are inversely as the radii. Experiments upon these lines which are believed to have only partly satisfied the above conditions have been made by Conette and Mallock.

But the point of greatest interest is not touched in the above arrangement. It arises when a fluid passing along a uniform or contracting pipe or channel arrives at the place where the pipe expands. If the expansion is sufficiently gradual the fluid, generally speaking, follows the walls, or, as it is often expressed, the pipe flows *full* and the loss of velocity accompanying the increase in section is represented by an augmentation of pressure approximately according to Bernouilli's law.

On the other hand, if the expansion is made violently, the fluid refuses to follow the walls; eddies result and mechanical energy is lost by fluid friction.

According to W. Froude this is due to loss of velocity near the walls in consequence of fluid friction, which is such that the fluid in question is unable to penetrate into what should be the region of the higher pressure beyond.

The writer proposes a comparatively simple experiment, which, while not fully satisfying all conditions, might throw interesting light upon the subject. It is proposed to observe the flow of liquid between two cylinders *A* and *B*, Fig. 8 (probably brass

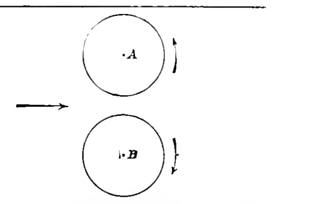

FIG. 8 DIAGRAM OF LORD RAYLEIGH'S PROPOSED HYDRAULIC EXPERIMENT

tubes) revolving about their axes in opposite directions. The circumferential velocity of the cylinders should not be less than that of irrotational fluid in contact with the walls at the narrowest place. The simple motion may be unstable, but the critical situation would be so quickly traversed that possibly the instability may be of little consequence. If no marked difference in the character of the flow could be detected by color streaks whether the cylinders were turning or not, the inference would be that Froude's explanation is inadequate. In the contrary event, the question would arise whether particular advantage could be taken by specially stimulating the motion of the fluid near the walls of expanding channels, as, for example, with the aid of steam jets. (*The London, Edinburgh & Dublin Philosophical Magazine*, vol. 36, no. 214, October 1918, pp. 315-316, 1 fig., *t*)

Internal-Combustion Engineering

INVESTIGATION OF THE GOVERNING OF A GAS ENGINE, Prof. A. Gramberg. The governing of a gas engine by throttling the mixture as shown diagrammatically in Fig. 9, differs fundamentally from the governing of a steam engine as described by the present author in another article. (See abstract in THE JOURNAL, November 1918, p. 967).

The governing of any power-producing engine is affected by the variation of the load on the engine. If the power-producing engine is a gas-engine generator set, as in the present instance, then the resistance W_A of the external circuit may be varied by introducing new resistances in parallel with the initial resistances. At the beginning of the no-load run the resistance of the external circuit is infinitely large, a fact which cannot conveniently be indicated diagrammatically. For this latter purpose, instead of the resistance it is more convenient to use the reciprocal of it $\frac{1}{W_A}$, or the conductance of the external circuit which at no load is equal to zero. In that case one measures the potential at the terminals of the generator in volts E and the current J.

With the increase in conductance, J and hence the output $N_{EL} = E\,J$ increase, and, therefore, the speed N in r.p.m. decreases.

The decrease of speed has as its consequence the decrease of the electromotive force of the generator with the increase of load, this electromotive force being proportional to the speed of rotation. The potential at the terminals decreases still more since the loss of potential in the armature of the dynamo increases with the current. The decrease of the terminal voltage E due to these two influences has to be equalized by manipulating the field rheostat and also by increasing the exciting current. This may continue until the field rheostat is entirely short circuited and the exciter winding is connected directly to the terminals. The exciting current in the generator under consideration may reach the maximum value $i_{max} = 1.05$ amperes at the terminal voltage of 220 volts.

The results of the tests are given in Figs. 10 and 11 and Table 2. In the first three tests, Nos. 89, 90 and 91, the transition was made in two broad steps from no load to full load and the rheostat had to be adjusted from contact point 3 to contact point 20 in order to maintain the potential, although the speed fell off from 192.0 to 186.7 r.p.m.

In the next test, No 92, the external conductance was raised only a little, viz., from 0.227 to 0.235 J_{E}, but although the rheostat was shifted previously the maximum output was exceeded. When in test No. 93 the rheostat was shifted from contact point 22 to 25, the desired potential could not be obtained. The governor went down and with it the speed of rotation, which brought the potential lower than the field rheostat was capable of handling.

If, finally, in tests 94 to 96 we set the field rheostat at its ultimate contact point 41 and then raise the conductance still more, we only succeed in reducing the speed, as the engine is then overloaded.

A peculiar feature of this whole phenomenon as compared with that of steam-engine governing is that only a small part of the stroke of the governor sleeve is utilized, viz., the heavy line in Fig. 10. At 192.0 r.p.m. the engine runs at no load and already at 186.7 r.p.m. the maximum load is reached while the governor is still 28 mm. above its lowermost position. Nevertheless, the further sinking of the governor does not produce any increase in load.

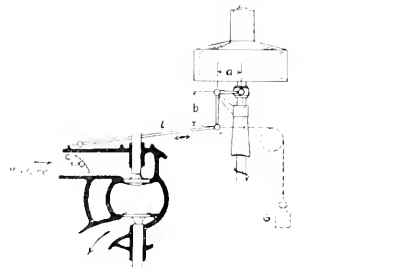

Fig. 9 Diagram of the Governor Arrangement on a Gas Engine

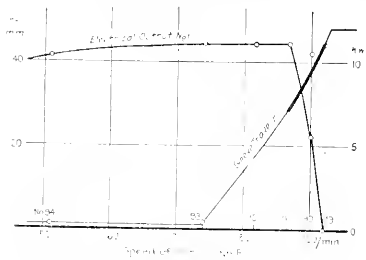

Fig. 10 Governor Curves Taken on Gas Engine

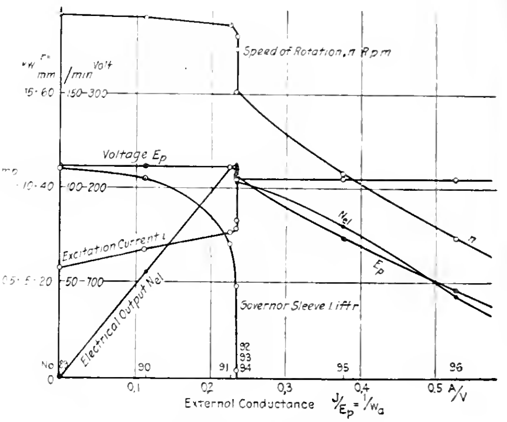

Fig. 11 Curves of Operation of an Automatically Governed Gas-Engine Generator Set

These facts represent the external appearance of the phenomenon; the inner reason wherefore the possible rise cannot exceed $\frac{1}{W_1} = 0.235$ is due to the transformation of energy. Up to test No. 91 the volumetric efficiency η_{vol} (as read from the indicator diagram) increases. In experiment 91 the volumetric efficiency is seen to be 0.985 and therefore cannot be materially increased. With the governor position $r = 28$ mm. above the lowermost position the throttle valve has already opened so far that the mixture does not meet with any material resistance, and the further opening of the throttle valve cannot produce any change in conditions. Hence, the further movement of the

governor is without effect: If the amount of fuel mixture introduced cannot be increased, a further supply of energy is made impossible.

Hence, in this instance, contrary to what happens in the case of the steam engine, the maximum output of the engine is governed not only by the governor and its appurtenances but by the engine itself.

Judging by Fig. 10 the governor is strongly static. It has a degree of lack of uniformity equal to

$$\frac{192.0 - 174.1}{\frac{1}{2} \cdot (192.0 + 174.1)} = 0.098$$

or 9.8 per cent. On the other hand, the governing itself is much less static, because it does not utilize the full range of the governor. Its coefficient of lack of uniformity is

$$\frac{192.0 - 186.7}{\frac{1}{2} \cdot (192.0 + 186.7)} = 0.028$$

or 2.8 per cent. It is therefore necessary to distinguish in this case the properties of governing from those of the governor.

One might presume that the governing, being practically astatic, would be subject to violent oscillations. This is not the case, however. Fig. 12 gives the tacho-diagram of the governing, which seems to be quite satisfactory, although at full load and no load the current interrupter was brought into play.

Lubrication

The Viscosity of Lubricating Oils, E. Oelschläger. (*Zeits. Vereines Deutsch. Ing.*, 62, pp. 422-427, July 6, 1918). The author, in this portion of his extended series of articles upon lubricating oils, deals with the relation between viscosity and temperature. He points out that it is customary to carry out the viscosity test at various temperatures according to the intended application of the oil, the usual test temperature for transformer oils being 80 deg. cent., and for bearing oils 50 deg. cent., and for cylinder oils 100 deg. cent. No formula or chart, however, has existed up to the present which would enable one to calculate the viscosity at any other temperature than that at which the observation was actually made.

As a result of an extended investigation of the results obtained with many oils, the author has constructed curve diagrams which overcome this difficulty. By aid of these, the viscosity of any oil can be ascertained for any temperature when one determination of it has been made. The only exceptions to the law governing the rate of change in the viscosity with temperature variations, are rape-seed oil, linseed oil, and blubber oil. (*Science Abstracts,* Section B—Electrical Engineering, vol. 21, pt. 9 (no. 249), Sept. 30, 1918, pp. 320-321. *eA*)

Machine Design (See also Internal-Combustion Engineering)

Efficiency of the Screw, Benjamin F. Groat, Mem.Am.Soc. M.E. An important article, for a complete abstract of which, unfortunately, there is not enough available space. It embodies an attempt to express in mathematical formulae the performance of various types of screws, so that a screw of given efficiency can be constructed from arbitrary dimensions.

Among other things, the writer tries to show that the torque upon a screw necessary to lift a given load cannot be determined by the use of a general coefficient and that each design has its own coefficient.

A screw is defined from the mechanical point of view as a machine which converts a torque into a thrust, or, inversely, a thrust into a torque. It acts as an intermediary between three external bodies, one of which may be considered to be a fulcrum and to be at rest. The mutual interactions between the other two bodies and the screw may then be considered under three different headings.

Case 1 (Fig. 13). The screw receives a torque from one of the bodies and converts a portion of that torque into an equivalent thrust, which it transmits to the other body. A jackscrew lifting a weight is an example of this case.

In Fig. 13 it should be understood that the nut is fixed while the screw turns and that θ = angle BPC and ϕ = angle CPA, which are respectively the angles of slope of threads and of friction.

In case 2 (Fig. 14) the screw receives a thrust from one of the bodies and converts a portion of that thrust into an equivalent torque, which it transmits to the other body. A "spiral" ratchet screwdriver affords one of the few examples of this case. The slope of the screw threads must exceed a certain minimum. Fig. 14 is generally similar to that of Fig. 13, but the angle of slope $\theta = BPC$ is numerically greater than the angle of friction $\phi = CPA$, and of contrary sense. There is a component AB of the resultant AP which *assists* the motion, and the motion must occur unless opposed by a torque upon the screw of sense contrary to the impending motion and to the component AB. A limit of this case is reached when $\phi = -\theta$, that is, when A falls upon B, which

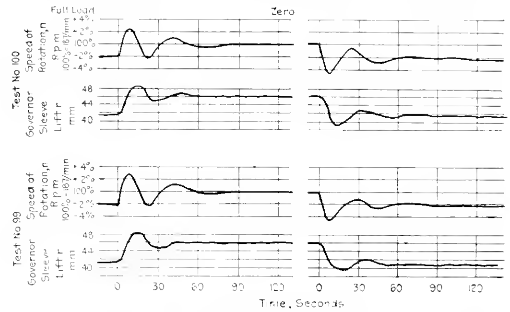

Fig. 12 Tacho-Diagrams of an Automatically Governed Gas-Engine Generator Set

implies that the screw locks and cannot turn unless assisted by an external torque.

Case 3 (Fig. 15). Here the screw receives a torque from one of the bodies and a thrust from the other, the combined work of both torque and thrust being consumed in friction. A jackscrew letting a weight down is an example of this case. The slope of the screw threads cannot exceed a certain maximum. In this case the point A falls to the left of B. The motion cannot occur unless assisted by an external torque upon the screw of the same sense as the motion, but, as in all cases, contrary to the component AB, which may be taken as a measure of the couple that must exist in the screw spindle in order to maintain uniform rotation; it should be remembered, however, that bearing friction is an additional element not yet taken into consideration.

The notation employed is as follows:

T = the thrust which is due to the reaction between the threads of the screw and the threads of the nut. It is not necessarily equal to the thrust delivered by the screw upon external bodies, considering the screw, nut and thrust bearing to be a self-contained unit. This is because the weights of parts of the screw may affect the action.

t = the thrust upon the thrust bearing. It is not necessarily equal to T, though, where the weights of the affecting parts of the screw are negligible, it is usually so considered. The relative values of T and t thus depend in each case upon the particular positions of the screw and the bodies acted upon.

M_t = the torque which is theoretically equivalent to the thrust, T, due to the reaction between the threads.

M = the actual torque passing between the screw or nut, as the case may be, and the body which receives or imparts torque.

M_s = the torque which exists in the body of the screw or of the nut, according as it is the screw or the nut which turns.

The writer calls attention to certain relations which may exist between M_t, M and M_s.

μ and ϕ are, respectively, the coefficient and angle of sliding friction for the threads. When thrust is being converted into torque (the weight descends) these quantities are both to be taken negative in the general formulæ. "It appears that for screws lubricated with oil, with pressures of $1\frac{1}{2}$ to 5 tons per square inch of projected area of screw thread, and for low speeds, the

coefficient is about 0.11 to 0.20 whether the screw or the nut are of steel, wrought iron, cast iron or bronze."—Unwin.

μ_1 and ϕ_1 are, respectively, the coefficient and angle of friction for the thrust bearing. They are probably somewhat less than the corresponding values for the threads. If the threads are not cut threads they may be considerably less. They are both negative in the general formulæ when the weight descends.

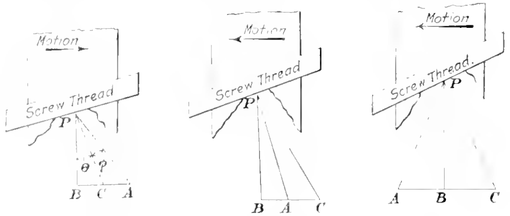
r = average radius of the screw threads or arm of frictional resistance acting upon the surface of the threads. No great error will be made if it is taken as the arithmetical mean of the inner and outer radii of the screw threads. If questions of elasticity are introduced, its exact determination becomes more difficult.

ρ = average radius (similar to that for r) of the pivot or collar.

n and θ are, respectively, the slope and the angle of inclination of the threads.

p = the axial pitch of the screw.

With the foregoing notation the following general formulæ concerning the square-threaded screw will be established:



Figs. 13, 14 and 15 Three Cases of Screw Operation

$$M_t = \frac{Tp}{2\pi} = Trn \qquad [1]$$

$$\frac{M_t}{M_s} = \frac{\tan\theta}{\tan(\theta+\phi)} = n\frac{1-\mu n}{m+\mu} \qquad [2]$$

$$\frac{M_s}{M} = \frac{1}{1+KA}$$

where $n = \tan\theta = p \div 2\pi r = p \div 6.283r$; and μ, μ_1, ϕ and ϕ_1 are to be taken negative when the weight is being let down or the screw slackened. Also in accordance with formula [3]:

$$K = \frac{\tan\phi}{\tan(\phi+\theta)} \qquad [4]$$

$$A = \frac{\mu_1}{\mu}\,\frac{t}{T}\,\frac{\rho}{r} \qquad [5]$$

The formulæ for the maximum compound efficiency of screw and thrust bearings are given as follows:

$$n = -D + \sqrt{D^2 + (D \div \mu)}$$

where

$$D = \frac{\mu(1+A)}{1-A\mu^2}$$

and $n = \tan\theta$ and the above formula gives the critical value of n.

Two tables are included in the original article giving the values of $\frac{M_t}{M_s}$, $\frac{M_s}{M_t}$ and K directly as functions of n and μ, and several cases where these formulæ can be applied are discussed in considerable detail. In particular the case of the application of these formulæ to V-threads and worm gearing is given.

In this latter connection the writer agrees fully with the conclusions arrived at by F. A. Halsey (Mem.Am.Soc.M.E.) in the *American Machinist* for 1898. At the same time he points out that both velocity and friction are vectors, that is, directed magnitudes, and unless they act in the same line it is only the projection of one upon the other which is effective. Because of this the writer believes that the compound thread friction and tooth friction of the worm and wheel are to be added geometrically and not arithmetically. In other words, the compound friction is less than the arithmetical sum of the thread and tooth frictions. In practice, the method described by the writer gives slopes much larger than are usually employed for the threads of worms, and this must be done, as far as practicable, where maximum efficiency is required.

In addition to this, the side thrust between the worm and worm-wheel should be taken into consideration. The side thrust of the wheel may be eliminated by employing right- and left-hand wheels and two worms. With two more wheels and worms the friction losses in the step bearings may be eliminated by properly disposing the right- and left-hand worms and wheels in neutralizing pairs.

Finally an arrangement is described which eliminates side thrust upon the journal bearings of the wheels, making it unnecessary to use ball bearings. This arrangement consists of two wheel shafts, four wheels, four worm shafts and eight worms, the efficiency being that of threads only.

Highly interesting test data which cannot be abstracted on account of lack of space are presented in the appendices. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 34, no. 5, June 1918, pp. 377-429, illustrated, *peA*)

Machine Shop

Manufacture of Transmission Chain, J. V. Hunter. Description of the plant and manufacturing processes of the Diamond Chain and Manufacturing Company of Indianapolis, Ind.

The company manufactures, in particular, a roller chain for drive between the various motors and lineshafts.

Part of the material used in the manufacture of roller chains comes in the form of rolled strips, but large quantities of round rod are used for pins and rollers, and figure-8-shaped cold rolled and drawn steel bars are used for block types of bicycle chains. Different grades of steel are used, depending on the part of the chain to be made, and also the service the chain must render. These grades vary from low-carbon dead-soft annealed steel to hard chrome-nickel steel.

An interesting operation, described in considerable detail, is the production of the side links. It is entirely a punching-machine job. The types of the links are shown in Fig. 16, where A illustrates the larger sizes used for truck drive and power transmission and B the smaller sizes for bicycle chain, etc. In the larger sizes, as A, a noticeable feature is the beveled edge, which one can see in the figure. In assembling, this beveled edge is turned inward on the inside links where it comes in contact with the sprocket teeth to avoid the tendency to cut and wear, and outward on the outside links, adding to the finished appearance of the chain.

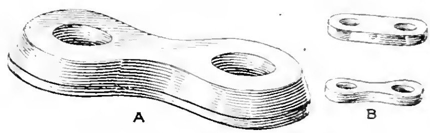


Fig. 16 Types of Side Links

A Bliss punching machine with an automatic feed attachment for advancing the stock after each stroke of the punch is used in the manufacture of these side links.

In the smaller sizes the holes are punched for the center of each link end before the links are blanked from the strip. In the larger sizes the links are blanked first, then beveled and in the last operation the holes are punched and shaved. All holes are shaved as the necessary clearance allowance on the dies results in a slightly tapered hole. The hole is purposely made from 0.012 to 0.015 in. under size and the shaving leaves the hole about 0.003 in. under the diameter of the pin that will be driven into it later.

For trimming the many millions of side links which are used in the manufacture of a lighter type of chain an automatic device illustrated in the original article is used. The links are fed into long tubes which act as a magazine in feeding these pieces to the trimming machines. To do this the links are poured into the funnel-shaped magazine, which, by means of a belt drive, is rapidly jolted up and down. In the center of this funnel is a tube which is forced up and down through the blanks contained

in it. This tube has an open end of the size of the end of the blank, and the jolting action forces these blanks to enter it one at a time, after which they slide lengthwise to a special mechanism. There a small ram pusher forces the blanks forward and into line with the magazine tube, into which another small pusher crowds them until the tube has been filled throughout its length. An extensive use of this magazine-filling device is made throughout the plant. (*American Machinist*, vol. 49, no. 15, October 10, 1918, pp. 643-647, 13 figs., *d*)

GENERATING CAMS AND IRREGULAR-SHAPED WORK, Douglas T. Hamilton, Mem.Am.Soc.M.E. Discussion of the capabilities of the gear shaper for generating cams or other irregular forms on a commercial basis.

The writer claims that the production of cams on the gear shaper is not only a simple proposition but is also accurate and fast, and that it is possible with the gear shaper to obtain, in a commercial way, cams that are very difficult to produce accurately by tool-making methods.

As shown in Fig. 17 the cutter used in producing the cam does not have anywhere near the same appearance as the cam itself. Fig. 18 shows, diagrammatically, how this form of cutter generates the cam. In operation the cutter and the cam blank are rotated in unison with each other and the rolling is done on two imaginary circles which are identical with the pitch circles of two gears in mesh. As the cutter and cam blank roll around in mesh with each other, the outline is generated on the cam as is illustrated by the fine lines in Fig. 18, these indicating the various positions of the cutter as it is rolled in contact with the blank. In connection

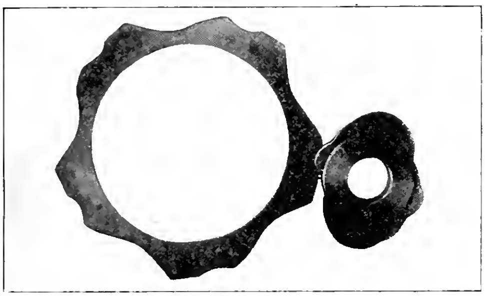

FIG. 17 EXHAUST CAM FOR GNOME ENGINE AND CUTTER USED IN PRODUCING IT

with this illustration, it is explained that the cutter has been rolled around the blank while the latter was stationary, this being done to simplify conditions and make the drawing clearer. In cutting these cam blanks a batch, preferably of eight blanks, is held in the fixture.

The article shows many interesting forms of cams, some of which would be very difficult to produce by milling, but are produced with comparative ease on the gear shaper. Among them is shown the breech block for a field gun upon which there is a series of interrupted gear teeth and a cam surface.

These examples are intended to show the successful application of the generating process, which is now used not only for cams proper but also for ratchets, milling cutters, etc., which were formerly produced by milling only. (*American Machinist*, vol. 49, no. 17, October 24, 1918, pp. 737-740, 12 figs., *pd*)

Machine Tools

SIMPLIFIED LATHE ADAPTED TO SHELL WORK. Description of the adaptation of the Gisholt 16 and 25 simplified lathes to munition work and of the various attachments used in that connection. An interesting feature of the new lathe is that, while it is made for a special purpose, the parts which enter into its several modifications have been standardized and reduced to a manufacturing basis.

The original article illustrates the machine in a rather interesting matter. First is shown what might be called a basic part: to wit, the bed, headstock, and parts always essential no matter for what operation the machine may be intended. Next is shown the machine equipped with a hand-operated collet chuck which may be mounted directly on the spindle nose close to the headstock in place of the faceplate and will accommodate work up to 6 in. in diameter. A carriage with a pillow-block support for the boring bar and center locking pin is also provided.

Then a semi-phantom view of the lathe is given. Shown in full size is the carriage with a 4-sided turret tool rest mounted on a right-angled compound cross-slide.

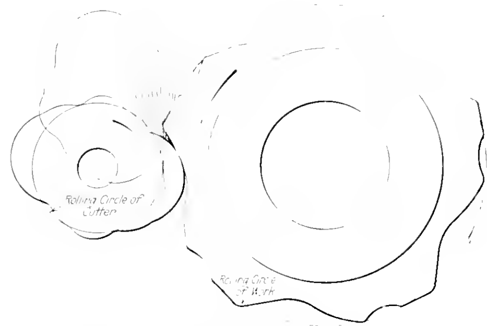

FIG. 18 DIAGRAM ILLUSTRATING HOW OUTLINE FOR CAM IN FIG. 17 IS DETERMINED

The other illustrations give the various attachments to the lathe. (*The Iron Age*, vol. 102, no. 16, October 17, 1918, pp. 945-948, 10 figs., *d*)

Measuring Instruments

COMBUSTION CONTROL METER. Description of a new system of instruments recently developed for facilitating the control of furnace combustion.

One of the features of this system is the application of a hollow tile to the bridge wall of a boiler. The principle of operation is as follows:

The hollow, self-cleaning tile is placed in the center of the bridge wall and near the top. Hot gases from the furnace are bypassed through the passage in the bridge wall to the rear of it. A hole is provided in the side wall of the furnace and extends into the hollow tile, and in it two base-metal thermocouples are inserted in such a manner that the ends of the thermocouples are out of the direct path of the flame and no ashes can accumulate in the pockets and around the couples.

One of the couples is connected to an indicating pyrometer placed on the boiler front in view of the fireman, and the other is connected to a recording pyrometer placed in the engineer's office or at some other point. On the same panel with this instrument is placed a 20-point rotary switch. The switch is so arranged that either the bridge wall or the uptake temperature may be read.

When a furnace meter indicates the temperature, it also indicates in an approximate manner the output of the boiler. With the damper wide open the maximum volume of the gas passes through the furnace. If there are holes in the fire, this volume is cooled and the pyrometer will register a lower degree of temperature. If the grate is clogged, the volume of air is reduced and the temperature is reduced, which is also registered on the chart of the recording pyrometer. Therefore, a high temperature registration on the chart not only indicates the degree of furnace efficiency, but gives a check on whether the boiler is producing a high or a low output.

The temperature graduations of the chart shown in Fig. 19 are in hundreds. The high peaks represent high furnace temperature. The chart record is composed of dots that are made at intervals of 30 seconds. When the furnace is fired at a point

below the peaks, less heat is lost and the average temperature is maintained at a high point. These dots show just what is taking place in the furnace.

The furnace meter gives a comparative temperature record of the gases in the furnace and the actual temperature of the gases in the uptake. The record of the uptake gases indicates the following: A high temperature shows one or all of three conditions; namely, dirty tubes, a hole in the baffles or excess of coal per square foot of grate surface. Low temperature indicates leaking setting, poor fuel or abnormal draft.

The record of the bridge-wall gases by comparative temperature shows the condition of the fire as indicated by the temperature line and spacing dots on the chart, the quality of coal used, method of firing the furnace and the opening and shutting of the damper. Physics

THE SPECIFIC HEAT AT LOW TEMPERATURES, IV, MEASUREMENTS OF THE SPECIFIC HEAT OF LIQUID HYDROGEN. PRELIMINARY RESULTS ON THE SPECIFIC HEAT OF SOLID HYDROGEN AND ON THE HEAT OF FUSION OF HYDROGEN, W. H. Keesom and H. K. Onnes. (*K. Akad. Amsterdam, Proc.* 20. 7. pp. 1000-1004, 1918. Comm. No. 153a from the Phys. Lab., Leyden)

The determinations were carried out as in the case of nitrogen. The results obtained were as shown in Table 4.

Preliminary determinations of the specific heat of solid hydrogen gave at T = 12.55 deg. K., the value 0.64. For the heat of fusion per gm. of hydrogen the mean value of 15 cal. (15 deg.) was obtained. (*Science Abstracts*, Section A Physics, vol. 21, pt. 9 (no. 249), Sept. 30, 1918, p. 379)

THE MEASUREMENT OF LOW TEMPERATURES, XXVII, VAPOR PRESSURES OF HYDROGEN IN THE NEIGHBORHOOD OF THE BOILING POINT AND BETWEEN THE BOILING-POINT AND THE CRITICAL TEMPERATURE. P. G. Cath and H. K. Onnes. (*K. Akad. Amsterdam, Proc.* 20. 7. pp. 991-999, and 20.8. pp. 1155-1159, 1918, Comm. no. 152a from the Phys. Lab., Leyden)

Previous determinations of the vapor pressure of hydrogen have been extended. For the measurement of temperature an improved helium thermometer was employed. The results obtained are summarized in the following table. The temperatures have been reduced to the absolute scale, using the corrections deduced from the Leyden determinations of the compressibility of helium.

In Table 3 the pressures are given in international cm. of mercury at 0 deg. cent., and in international atmospheres respectively, the international atmosphere at Leyden being taken equal to 75.9488 cm. Hg. at 0 deg. cent. The vapor pressure can be satisfactorily represented by the equation (ρ being expressed in international atmospheres).

$$T \log \rho = -56.605 + 3.8015\,T + 0.10458\,T^2 + 0.003321\,T^3 - 0.00005102\,T^4$$

In the measurements at $\theta = 244.70$ and $\theta = 243.22$, the deviations are greater than might have been expected, and it is assumed that some unexplained experimental error must be present. A redetermination of the boiling point gave the value T = 20.39 deg. K. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 9 (no. 249), Sept. 30, 1918, p. 377, *eA*)

ULTRAMICROSCOPIC INVESTIGATION OF VERY THIN METAL FILMS OBTAINED BY EVAPORATION IN A HIGH VACUUM. W. Reinders and L. Hamburger. (*K. Akad. Amsterdam, Proc.* 20, 8. pp. 1135-1154, 1918).

This is a continuation of previous investigations, a method being here described by which the metal films can be protected by films of either calcium fluoride or Canada balsam or both while still in a vacuum. The elements investigated were W, Mo, Pt, Fe, Ni, Au, Ag, Mg, Zn, Cd, and C. The elements of high melting point, W. C, Mo. Pt. Ni, and Fe, give films which are optically either completely non-resolvable (W, C, Pt, and Fe), or for the most part non-resolvable with another part containing distinctly separate particles. The elements of lower melting point, Au, Ag, Cu, Mg, Zn, and Cd, show a far greater tendency to give a film consisting of a connected network of ultra-microns. The conclusion is drawn that in proportion as the temperature of incandescence required for slow sublimation is higher, the finer the structure of the sublimate (film) formed. Experiments in which the temperature of the glass on which the film was deposited

TABLE 4—SPECIFIC HEAT OF LIQUID HYDROGEN

Quantity of Hydrogen in Gm.	Mean Temperature	Specific Heat of Hydrogen in Cals. 15 deg. per degree K.	Atomic Heat in Cals. 15 deg. per degree K.
2.89	16.03$_5$	1.87	1.88
3.17	15.81	1.70	1.71
3.17	16.80	1.84	1.85$_5$
3.52	14.71	1.67	1.68
3.52	15.38	1.78	1.79
3.50	14.82$_5$	1.74	1.75
3.50	16.30	1.85	1.87
3.50	17.63	1.99	2.00
3.50	18.67	2.08	2.09
3.50	19.41	2.18	2.20
3.50	20.11	2.24	2.26
3.51	15.24$_5$	1.84	1.82
3.51	16.37	1.90	1.89
3.51	17.37$_5$	1.99	1.98
3.51	19.07	2.17	2.16

was varied, showed that the greater the vapor pressure of the metal at the temperature of the glass on which it is deposited, the coarser is the structure of the deposit. Various grades of coarseness can be observed, varying from deposits which are optically non-resolvable to deposits on which the smaller particles are distinctly separate.

W, Mo, C, Fe, Ni, and Pt give colorless films, whereas the other elements give colored films which, in the case of Ag, Au, and Cu, may show a great wealth of color. The color does not depend directly on the structure of the metal. For example, Au, Ag, and Cu show the same sequence of colors in mosaic deposits at room temperatures as in the structureless deposits formed at the temperature of liquid air. No coloring sets in with Pt, W and Fe when the structureless deposit is transformed into a mosaic deposit by local heating. The conclusion is drawn that the capacity for displaying color is an individual property of the metal and is determined by the selective absorption of the atoms. (*Science Abstracts,* Section A—Physics, vol. 21, pt. 9 (no. 249), Sept. 30, 1918, p. 350, *e*)

Power Plants

A New 25,000-Kw. Power Plant for Dayton, Ohio. Description of a station laid out to house 100,000 kw., but now having a capacity of 25,000 kw. in two units.

The turbines are of the nine-stage horizontal impulse type making 1800 r.p.m. At 200 lb. gage pressure, 125 deg. superheat and a vacuum of 29 in., these units are guaranteed to produce a kilowatt hour at half load on 12.4 lb. of steam; at three-quarter load, 11.95, and at full load, 12.4 lb.; (only the first value is apparently guaranteed).

The condensers are of the two-pass surface type, each containing 15,000 sq. ft. of tube surface, or 1.2 sq. ft. of surface per kilowatt of generator rating. The circulating pumps are mounted on the intake pipe, and are driven by a motor at one end of the shaft and a turbine with reduction gearing at the other end. Each drive may be used as dictated by exhaust-steam requirements to maintain the hot balance of the station.

An interesting feature in connection with the condenser installation is the arrangement for supplying circulating water. In this case, instead of the usual long, upstream intake, an intake basin has been constructed by the dragline method measuring 60 x 330 ft. and about 12 ft. deep. The mouth of the basic points downstream, so that the current of the river does not flow into it. This obviates much of the trouble usually encountered from gravel, driftwood and sewage, and also provides short intake tunnels.

The turbines are served by three boilers arranged in line along a firing aisle parallel to the turbine room, instead of at right angles to it, which gives a more symmetrical design. The boilers are of the cross-drum type, each having 13,730 sq. ft. of steam-making surface, so that one boiler horsepower supplies 6 kw. of generating capacity, a ratio exceedingly high, unless future provision is to be made for reserve capacity.

Special attention has been paid to the coal-handling apparatus, which consists of a steam hoist operating a clamshell bucket discharging into a hopper above the bunkers. From the hopper the coal passes through a motor-driven crusher into a cable car, where it is weighed before being passed to the steel bunker over the boilers. The system is rated at 90 tons per hour and is large enough to serve half of the ultimate plant. The ashes from the hoppers under the stokers are delivered by gravity into side-dump cars, which are hauled out to the low ground around the station by a gasoline-engine-driven tractor.

The water supply for the station is taken from wells, and, as it is unfit for boiler use without treatment, a hot-process water softener was installed to take care of the makeup, which was estimated to amount to about 2 per cent of the total water evaporated.

To keep down the size of the water-softening equipment a 10,000-gallon tank was placed on the roof of the building. It is supplied with condensate from a concrete tank in the basement by means of two 100-gallon-per-minute pumps, the operation of which is controlled by a float valve in the roof tank.

The water from the softener, which is heated to 200 deg. fahr., goes directly to the heater whenever the water level in the concrete overflow tank for the heater is lowered. The softener is of the Vater type, and is capable of treating 3000 gallons of water per hour as it comes from the wells (about 26 grains of hardness per gal). (*Power,* vol. 48, no. 18, October 29, 1918, pp. 620-624, 3 figs., *d*).

Railroad Engineering

The Locomotive Feedwater Heater. "The more extended use of the feedwater heater in locomotive service is awaited with confidence as to its ability to effect a saving of from 15 to 20 per cent in fuel, in accordance with results which have already been obtained in laboratory tests."

The editorial which starts with the above quotation makes a further claim that feedwater heating is especially adaptable to locomotive service.

On a locomotive the closed feedwater heater acts as a condenser used, however, rather for the purpose of condensing raw water to be used as boiler feed. The exhaust steam admitted to the heater is at such a low pressure that the greater portion of the heat contained therein is latent heat, which on being abstracted leaves the steam in the form of water at or near the boiling temperature. Were it not for the oil content in this water it would be of advantage to return it to the boiler, as then it would in itself constitute an increase of nearly one per cent in the overall efficiency of the machine. In time, with the improvement in the lubricating methods, it may, indeed, become possible to avail ourselves of this possibility.

In stationary feedwater heaters the condensation of steam on the surface of the tubes prevents the contact of additional steam with these tubes and serves to insulate them to an appreciable extent. In locomotive service the tubes are more rapidly freed of this condensation, because of the jarring of the engine as it passes over the track. This feature of rapidly freeing the tubes of condensation is of such importance that in stationary installations vertical instead of horizontal heaters are frequently used, and experiments are being made with heaters having lead-, zinc- and amalgam-covered tubes to which the water adheres less tenaciously than to steel or brass.

A feedwater heater also has an effect on increasing the output of a locomotive through reduction in back pressure. The abstraction of 14 per cent of the steam from the exhaust passage before the steam undergoes the choking effect at the nozzle, is equivalent to an increase in the size of the nozzle, since a lesser amount of steam (86 per cent instead of 100) is required to find its way through the passage. This phenomenon is unmistakably evident from indicator cards and dynamometer diagrams secured in locomotive tests. (Editorial in *Railway Review,* vol. 63, no. 15, October 12, 1918, p. 541, *gp*)

Refrigeration

Refrigerating Plant at the Intermediate Depot for the American Army in France, Robt. K. Tomlin, Jr. Description of the refrigerating plant at the Intermediate Depot for the American Army in France, designed to care for storage of 5000 tons of meat.

The plant is of a very large size, consisting of a group of twelve principal buildings, several miscellaneous buildings and a concrete reservoir 55 x 60 ft. in plan. The engine-, boiler- and pump-room equipment comprises eight 250-hp. horizontal tubular boilers, four refrigerating machines having a total capacity of 1100 tons of refrigeration, two 150 kva. electric generators and three turbine-driven centrifugal pumps, each with a capacity of 180 gallons per minute.

Refrigeration is by direct expansion of the ammonia circulating in coils hung from the ceiling of the building, which is divided into five rooms, each with a capacity of about 1000 tons of meat.

The designs for the plant were prepared at Washington, but simultaneously on the spot a so-called Ice Plant Company was organized of engineers, about 350 men strong, most of whom were recruited from the personnel of the large packing companies of the Middle West. The work was started in France in December, 1917, and, notwithstanding all the difficulties that surrounded construction work in France in those days, the plant was placed in operation on May 2, 1918, which is certainly an excellent record for a plant of that size.

There are certain features of construction which appear to be of special interest. Thus unusual pains have been taken to insure flexibility in the layout of the piping. A break in the piping would be especially serious, as in France ammonia losses would not be easy to replace. The ammonia lines are sectionalized by the installation of valves at frequent intervals, so that in case of a break a section of piping may be cut out of the system and ammonia losses thereby reduced.

Further, zero temperature is maintained in the freezing room. This fact, in connection with allowing meat to remain there for four days before shipment, makes it possible to dispense with special refrigerating cars and to forward the frozen meat in plain box cars. This feature of plant operation is of exceedingly great importance in view of the present car shortage in France and the undesirability of introducing special purpose rolling stock. (*Power*, vol. 48, no. 17, October 22, 1918, pp. 596-598, 4 figs., *d*)

Testing and Measurements

Electric Dynamometers for Aircraft Engine Testing. Description of very large dynamometers developed for testing the Liberty engine and other big aircraft power plants. Such dynamometers became necessary after it was found that the so-called club test (by means of a calibrated propeller) did not prove reliable. Two Sprague dynamometers are described in the present article. One size has a nominal rating of 300 hp. at 1325 r.p.m. and a maximum rating of 450 hp. at 1700 r.p.m. A smaller machine has also been developed with a nominal rating of 200 hp. at 1300 r.p.m. and a maximum rating of 300 hp. at 1650 r.p.m.

Combinations are frequently made of two of the smaller machines for testing up to 500 hp. and of two of the larger machines for testing up to 800 hp. For such combinations the electric control and torque-measuring system have been worked out so that the torque is read on a single scale and the load is controlled by a single handle just as in a single-unit machine.

In conducting dynamometer tests it is important that the loads at different speeds follow approximately the speed-horsepower curve of the propeller that would be used with the engine. This follows the cube law. It is claimed that results obtained on torque stands with clubs frequently vary as much as 10 or 20 per cent from the true horsepower output. With electric dynamometers much greater accuracy is secured.

A recent application of the electric dynamometer is for the making of efficiency and endurance tests on propellers. The dynamometer is used as a driving motor and the propeller is mounted upon a sliding shaft coupled to the dynamometer in such a manner that not only the torque required to drive the propeller is measured but the thrust or reaction is indicated. This arrangement is proving of great value in making overspeed tests on propellers. (*Automotive Industries*, vol. 39, no. 16, Oct. 17, 1918, pp. 675-677 and 696, 5 figs., *dp*)

0 Deg. or 20 Deg., or 0 Deg. and 20 Deg. (Pure Normal Temperature or Normal Temperature and Standard Temperature), F. Plato. (*Zeitsschrift Instrumentenk., Beib.* nos. 9, 10, pp. 49-54, May 5, 11, and 12, pp. 61-66, June 15, 1918) So long as instruments exist whose readings are dependent on temperature, there will be a need for fixing a particular temperature for reference. When the choice of this temperature is restricted to a select circle, then we speak of a standard temperature, but when state recognition is given, or international sanction is obtained, then the standard becomes a normal temperature. A large number of normal temperatures are in existence, but of these only two (of French origin) are not arbitrary, namely: the temperature of melting ice, and 15 deg. cent. (proposed by Gay-Lussac as the average temperature of the earth). The present paper contains a discussion of the various temperatures in the neighborhood of 15 deg. cent. which have been proposed from time to time. For many purposes 20 deg. has been found very convenient, and the advantages together with the drawbacks are dealt with at some length. The discussion includes that of other units in different systems. Section 1 considers the temperature of melting ice as a natural phenomenon. Section 2 treats the latter from the standpoint of requiring no thermal measure for its determination. In section 3 its independence with respect to temperature scales is examined. Here the various thermometric scales come under review. In section 4 the temperature of melting ice as a starting-point is shown as a safeguard against sign errors. In section 5 the possibility of international agreement to this temperature as normal temperature is discussed. The different national temperatures are here described. Following this comes an exhaustive discussion on the question of adopting 20 deg. cent. as a special standard temperature which would be especially beneficial to industry. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 9 (no. 249), Sept. 30, 1918, pp. 377-378, *g*)

The Relationship of Impact Value to Maximum Stress, Elongation and Brinell Hardness, G. Berudt. (*Zeits. Vereines Deutsch. Ingenieure*, no. 62, pp. 421-422, July 6, 1918) The impact value was measured of some 40 samples of basic Siemens steels of which the elastic limit, maximum stress, percentage elongation, and Brinell hardness were all known. With the exception of the elongation these values at first increased as the impact value rose, reaching a maximum with an impact value of 1.3 kg-m., after which they decreased rapidly and became finally more or less stationary. The impact value, which is of all the properties measured the most sensitive in detecting brittleness, appears to increase with the ferrite content of the steel. Two photomicrographs are included. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 9 (no. 249), Sept. 30, 1918, p 347, *t*)

Thermodynamics

The Joule-Thomson Effect and the Equation of State for Gases at Small Pressures, M. Jakob. (*Ann. d. Physik*, 55. 7. pp. 527-544, June 21, 1918. From the *Physikal-Techn. Reichanstalt*). From Planck's partial differential equation

$$\frac{10^4\,T^2}{427}\left(\frac{\partial\, v\,T}{\partial\, T}\right)_p = (c_p)_0\left(\frac{\partial\,\Delta}{\partial\, p}\right)T,$$

the equation of state of a gas may be derived if, besides its specific heat $(c_p)_0$ for $p = 0$, the integral Joule-Thomson effect Δ for an infinitesimal pressure is given as a function of the initial pressure p (kg./cm.²) and the temperature T, also an isothermal of the state is given for the determination of the arbitrary integration function when the integration is made with respect to T. From the throttle experiments of Bradley and Hale, and of Noell for air, the empirical equation $(\partial\Delta/\partial p)\,T = Ap^3 + Bp^2 + Cp + D$ was obtained, wherein A, B, C, D are simple rational func-

tions of T. From these equations and an isothermal by Amagat and Holborn and Schulze follows the equation of state: $v = \mathrm{R}\ \mathrm{T}/10^4 p + \mathrm{A}'\, p^3 + \mathrm{B}'\, p^2 + \mathrm{C}'\, p + \mathrm{D}' + \mathrm{E}'\ \mathrm{T}$, where R is the gas-constant, and A′, B′, C′, D′ are similar functions of T as A, B, C, D. E′ is a determined rational integral function of p. The author has found this equation of state valid at high pressures, *e.g.* at — 140 deg. cent. up to 30 atmos., at — 80 deg. cent. to 200, at 0 deg. to 700, at 200 deg. to 1000 atmos. The relations at very low pressures have been considered, and for $p = $ the following equation evolved: $\partial\,(pv)\ /\ \partial\, p = \mathrm{D}' = -\ 191310/\mathrm{T}^4 + 10229/\mathrm{T}^3 + 147.63/\mathrm{T}^2 + 0.08973\ \mathrm{T} + 0.00065708$. This equation is established in the present paper and compared with known experimental data. This comparison gives a sharp criterion as to the validity of the above equation of state for very small pressures, and between what temperature limits. It is shown that the last equation holds good for other gases after the introduction of the necessary data. Section 2 of the paper deals with the inadmissibility of the identification of an ideal and of a real but infinitely diluted gas. Section 3 develops the equations of state and the Joule-Thomson effect according to van der Waals and Berthelot are considered. The Joule-Thomson effect of infinitely dilute air according to theory and experiment, forms the subject of section 5. Section 6 deals with the derivation of a real but infinitely dilute gas from Mariotte's law. In section 7 the Joule-Thomson effect of other gases is calculated from that of air, according to the method of corresponding states. The equation of state is found to hold for very low pressures as for very high, and so to be of general applicability. (*Science Abstracts,* Section A—Physics, vol. 21, pt. 9 (no. 249), Sept. 30, 1918, p. 381)

NEW HEAT-TRANSMISSION TABLES, Wm. R. Jones, Mem.Am. Soc.M.E. A compilation of factors of heat transmission through various classes of building materials, with index of authorities quoted.

The materials considered cover glass, single, double and various types of skylights; various types of walls, such as brick, brick and plaster, concrete, as well as tiles, etc.

The tables represent apparently a very large amount of work and are of considerable interest. (*Heating and Ventilating Magazine,* vol. 15, no. 10, October 1918, pp. 36 to 41, *gpA*)

Varia

GOVERNMENT COMMISSION COMPOSED ENTIRELY OF ENGINEERS. During the past summer, the New Brunswick government appointed a commission to investigate the water-power situation in that province. The appointment of such a commission is, of course, not unusual, and would not warrant special notice except for the fact that this commission, contrary to the usual custom in appointing various government commissions, consists entirely of engineers. C. O. Foss, chairman of the commission, has been connected with the Canadian Society of Civil Engineers and The Engineering Institute for a great many years. He is chief engineer of the St. John and Quebec Railway. B. M. Hill, a member of the commission, is provincial engineer. Mr. Hill is an engineer who has taken considerable interest in public affairs, and at one time contested a seat in the local legislature. W. E. McMullen, secretary of the commission, is the engineer of the Crown Lands Department.

This commission is acting in coöperation with the Dominion Water Power Branch, so that the technical aspects of the water-power situation in both the provinces of Nova Scotia and New Brunswick are being handled by a single engineering organization, which results in maximum efficiency and economy. Although the New Brunswick Water Power Commission was not in a position to begin active operations until early in August last, already eleven stream-measurement stations have been established in various parts of the province and an adequate foundation laid for obtaining basic stream-flow data in various parts of the province. (*Journal of The Engineering Institute of Canada,* vol. 1, no. 7, November 1918, p. 336, *g*)

EFFECT OF AIR TOOLS ON WORKMEN. At the congress of the National Safety Council in St. Louis, September 18-19, a paper under the above title was presented by Francis M. Barnes, Jr., covering reports of several investigations carried out recently.

The following conclusions are drawn by the writer, and he himself acknowledges that they are subject to some limitations because they are drawn from a comparatively small series of observations:

1 Structural-steel workers, shipbuilders and stone cutters, as a class, enjoy good general health, and are not, because of their trade, especially susceptible to any particular disease.

2 Stone cutters are liable to a disorder affecting the hands, especially the left hand.

3 This disorder of the hands is of a vascular character, not due to organic changes in the circulatory system, but dependent upon vasomotor reactions.

4 These reactions are physiological in character and are occasioned by three factors incident to the work of stone cutting: mechanical irritation of the skin, continued muscular contraction of a cramping nature, and low temperature.

5 Of these three factors, cold is considered the most important because the condition only occurs during the severely cold weather and never in the summer, and warmth and measures to restore the circulation (rubbing, swinging the arms, and the like) cause its disappearance.

6 It cannot be caused by the effect of the air hammer alone, because it occurs in those who have not used the air hammer. It does not occur in warm weather when industry is at its height, and, therefore, when the air hammer is most in use. It occurs mostly in the left hand, and not in the right in which the hammer is held.

7 The vasomotor disorder is of temporary duration, and is not known to have resulted in permanent disability of the hand, nor itself to have been the cause of development of any other local or constitutional disease.

8 It is possible that once having occurred, the person is rendered more susceptible to its reappearance, just as is the one who has had his ears or fingers frostbitten by the cold.

9 There is no sufficient reason in the signs and symptoms presented in this disorder to conclude that one has to do with Raynaud's disease, acroparesthesia, neuritis or an occupational neurosis.

10 The institution of measures to warm the chisel before and while using, enlarging the shank of the chisel and covering it to make it possible to hold without so cramping a grip, the wearing of gloves, and the discontinuance of the prevalent custom of blocking the exhaust outlet, and thus forcing a draft of chilled air out along the chisel and onto the fingers of the left hand, would do much toward the prevention of this trouble. (*The Iron Trade Review,* vol. 73, no. 19, November 7, 1918, pp. 1071-1072, *g*)

NEW YORK-CHICAGO AIR-MAIL ROUTE. Postmaster-General Burleson announces that the New York-Chicago air-mail route will be inaugurated between December 1 and December 15. The exact time of the establishment of the service will depend upon the time of the receipt of the Post Office Department of the necessary airplanes to operate the line.

The route will be laid out in three legs; the first from New York to Bellefonte, Pa., a distance of 215 miles, with an emergency station and machine midway to Lehighton; the second leg from Bellefonte to Cleveland, a distance of 215 miles, with an emergency station at Clarion, Pa., a distance of 87 miles from Bellefonte; the third leg from Cleveland to Chicago, a distance of 323 miles, with an intermediary mailing station at Bryan, O. (*Official Bulletin,* October 25, 1918, p. 1)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

The world war has changed for most every one his point of view of life, and it should particularly change the motives of the engineer. He has rendered indispensable service in the world war, and is properly receiving the credit therefor. The opportunity offered him by reconstruction is many fold greater than that he has had in the military operations.

Mr. Charles M. Schwab, at his reception in the Metropolitan Opera House, Philadelphia, to the members of the staff of the Home Office of the Emergency Fleet Corporation, said that "the measure of a man's worth is the service he renders." This was the rejoinder to a remark by the Secretary of the Navy, that Mr. Schwab was so rich that he didn't want any more money, whereas the Secretary of the Navy was so poor that he wouldn't know what to do if he had money.

Mr. André Tardieu, the Minister of Franco-American War Affairs in the French Cabinet, has just arrived again in this country, and frankly invites this nation to "assist France to her feet."

The Society is in receipt of an invitation from President Millerand, of the Congrés Général du Genié Civil, which is to take place in Paris the middle of December, to send a delegate and assist in conferences with respect to reconstruction problems. These problems obviously will be mainly of civil engineering, and it is probable that the representatives of that branch of engineering will form the largest part of the delegation, but there are numerous phases of particular interest to mechanical engineering on which our delegate can help, and the Secretary takes this means of soliciting suggestions and volunteers of service not only for this but any others on which the Society may call when occasion arises.

I have already mentioned in my previous letter the visit of the delegation from the Government of Belgium which has just returned. I have also had a call this month from the Governmental representative of Holland, who was seeking advice with respect to the development of water powers, and general information on opportunities in industrial development for Holland's colonies.

The spirit of the Society must be that of the individual. How can we render the greatest service to the world? At the Annual Meeting we are to have several addresses which will assist our members by way of suggestion.

Along these lines it is with particular satisfaction that I can announce the formation of the American Engineering Standards Committee, which in organization and scope of work is parallel to the wonderful British Engineering Standards Association. With the development of our relations with all countries, the need for standardization becomes still greater, particularly with our desire for foreign trade. Standardization is absolutely essential to trade, particularly of the type in which we in the United States are especially successful, namely, the production of articles in great quantities.

With the opening of the new hopes for all peoples for greater opportunity of self-development comes the same opportunity to the engineering profession in its peculiar and specialized work.

The Secretary solicits correspondence with members who are desirous of participating in this greater movement.

Calvin W. Rice,
Secretary.

Council Notes

A Meeting of the Council was held on the afternoon of Friday, November 8, 1918, in the rooms of the Society. There were present: Charles T. Main, *President*, H. de B. Parsons, R. H. Fernald, Arthur M. Greene, Jr., Spencer Miller, C. H. Benjamin, D. Robert Yarnall, Wm. H. Wiley, *Treasurer*, Ira N. Hollis, Charles T. Plunkett, D. S. Jacobus, George M. Forrest, *Chairman Finance Committee*, Jesse M. Smith, *Chairman Committee on Constitution and By-Laws*, George A. Orrok, *Chairman Publication and Papers Committee*, Calvin W. Rice, *Secretary*, and by invitation, George J. Foran, *Chairman Engineering Resources Committee.*

Business from the President

Rehabilitation of Wounded and Readjustment of Industries to Peace. The President was authorized to appoint a committee to take up the question of the way in which this Society can best assist in the reconstruction problems after the war, the readjustment of the industries, and coöperation in war relief work, including the American Red Cross.

Invitation to Paris Conference. The President reported an invitation from the Société des Ingénieurs Civils de France, to this Society to send a delegate to an Engineering Congress to be held in Paris, in December. As announced elsewhere, by subsequent action of the Executive Committee, President Main was appointed to represent the Society at this conference.

Standing Committees on Administration

The annual reports of these committees were received and ordered printed. They appear elsewhere in this issue of The Journal.

Membership Committee. Under By-Law 16 the remission of dues of the following members who have either paid for 35 years or reached the age of 70 and paid for 30 years was recorded:

Albrecht, Otto.	Emery, A. H.	Sellers, C., Jr.
Alden, Geo. I.	Forsyth, R.	Smith, A. W.
Allen, F. B.	Forsyth, W.	Smith, G. H.
Angstrom, Carl.	Halsey, F. A.	Smith, Oberlin.
Baldwin, Wm. J.	Henry, Wm. T.	Stangland, B. F.
Ball, F. H.	Herrick, J. A.	Stearns, T. B.
Bancroft, J. S.	Higgins, Geo. F.	Stratton, E. P.
Barnes, W. F.	Hill, Wm.	Suter, Geo. A.
Barrus, Geo. H.	Hollerith, H.	Swain, G. F.
Betts, A.	Howard, C. P.	Tallman, F. G.
Bilgram, Hugo	Hugo, T. W.	Taylor, Stevenson.
Bond, Geo. M.	Hunt, R. W.	Thomas, E. W.
Brooks, E. C.	Landreth, O. H.	Thorne, Wm. H.
Burdsall, E.	Lanza, Gaetano.	Townsend, David.
Byllesby, H. M.	McEwan, J. H.	Trump, E. N.
Capen, Thos. W.	McFarland, W. M.	Walworth, A. C.
Carpenter, R. C.	Martens, F.	Warner, W. R.
Cheney, W. L.	Marx, Henry.	Webber, H.
Clarke, Chas. L.	May, DeCourcy.	Webster, H.
Cloud, John W.	Miller, L. B.	Weston, E.
Cogswell, Wm. B.	Mullen, John.	White, J. J.
Coon, J. S.	Newcomb, Chas. L.	Whitham, J. M.
Cox, J. D.	Porter, H. F. J.	Wiley, W. H.
Dean, F. W.	Raynal, A. H.	Wood, W.
Durand, W. F.	Scheffler, F. A.	Worthington, C. C.

Finance Committee. The Secretary reported the death of Mr. R. M. Dixon, *Chairman*, and the following resolutions were ordered entered on the minutes:

Resolved: That in the death of Robert M. Dixon, for ten years a member of the Finance Committee and for more than eight years its Chairman, the Society has lost one of its most valued members, and a leader whose wise counsels and mature judgment contributed in a most conspicuous manner to the present sound financial condition of our Society, which is in itself a most flattering tribute to the financial and executive ability of the engineer, the citizen, and lovable companion, whose loss we mourn. And be it further

Resolved: That a copy of these resolutions be spread upon the minutes of this meeting and a copy properly amplified with historical data be engrossed for presentation to the family of Mr. Dixon, and for publication in The Journal and Transactions of the Society.

On recommendation of the Publication Committee, approved by the Finance Committee, the purchase of "The Engineering Index" from Industrial Management, was authorized.

The President announced that the Committee had selected Mr. George M. Forrest to act as Chairman and he had appointed Mr. Frank E. Law to fill the unexpired term of Robert M. Dixon.

Meetings Committee. On the recommendation of this committee, the status of the sub-committee on Protection of Industrial Workers was changed to that of a special committee.

Standing Committees

The annual reports of the Standing Committees on *Library, House, Research, Standardization and Public Relations* were received.

Standardization Committee. The Secretary reported the appointment of Clifford B. LePage, Assistant Professor of Physics at Stevens Institute of Technology, as Acting Secretary of the American Engineering Standards Committee, in addition to the work which Mr. LePage was doing in the Society as secretary of all the technical committees.

Professional Committees

Patents Committee. The report of Mr. E. J. Prindle, representative of the Society on the Patents Committee of the Engineering Council, was received.

Refrigeration. The progress report of Dr. D. S. Jacobus, Chairman of the Refrigeration Committee, was received.

Power Test Committee. The resignation of Mr. George H. Barrus was accepted. Mr. Barrus was thanked for his services to the Society.

Sub-Committee of Fuels. On the recommendation of Prof. Charles Russ Richards, this committee, which was appointed to act in an advisory capacity to the Bureau of Mines, was discharged with thanks.

Boiler Code. This committee as now constituted was continued for one year.

The Council received a delegation from the National Boiler and Radiator Manufacturers' Association in the matter of Par. 363 and 374 of the Code relating to heating boilers.

The Boiler Code Committee was requested to keep before them these two articles, and should the state of the art prove that either of them is inadvisable, action is to be taken by the committee to rectify them. This action was ordered communicated to the representatives of the Association.

Interpretations Nos. 200 to 206 were approved.

Increase of Membership. The report of this committee was received. This report carried with it the appointment on this committee of Mr. G. M. Forrest, Chairman of the Finance Committee.

Special Committees

Emergency War Training. This committee was discharged with thanks.

Engineering Education. The report of the Committee on Engineering Education, as given in A Study of Engineering Education, by Dr. Charles R. Mann, printed under the auspices of the Carnegie Foundation for the Advancement of Teaching, was received and the committee of this Society discharged with thanks.

Appointments

By the President. W. W. Macon, H. L. Aldrich, A. J. Baldwin on a delegation of technical editors to England as the guests of the British Ministry of Information.

F. R. Low, Chairman, George H. Barrus and H. L. Gantt, to prepare a memorial to the late Mr. William Kent.

By the Council. Walter M. McFarland to fill the unexpired term of two years of R. M. Dixon, as Trustee of United Engineering Society.

The Council approved the principle of the appointment on the Engineering Council of the President of the Society during his term of office.

M. E. Cooley, nominee for President, was appointed for one year.

George J. Foran, reappointment on the Engineering Council for three years.

Adjournment. To meet in New York City, on Tuesday, December 3, 1918, at 2 p.m., in connection with the Annual Meeting.

Calvin W. Rice,
Secretary.

President Main to Go to France

The American Society of Civil Engineers some time ago received an invitation coming through the Société des Ingénieurs Civils, and the Committee of the French Engineers' Congress, with the official approval of the French Minister of Armament, Public Works and Commerce, requesting it to arrange for a delegation of American engineers to study with French engineers certain problems involved in the rehabilitation of France after the war.

This delegation was invited to come to Paris to examine in joint conference questions of utilization of commercial ports, development of navigable waterways, development of water power, and improvement of road systems. These were the only specific subjects mentioned, but it is known that the Congress will take up many other questions of development in which the mechanical, electrical and mining engineer is directly interested.

Upon receipt of this invitation a cable was forwarded by the A.S.C.E. accepting the invitation, and stating that they would organize such a delegation in coöperation with the other American National Societies.

The American Society of Mechanical Engineers, through its Executive Committee, designated President Main to become a member of this official delegation.

Index to the 1918 Journal

An index to Vol. 40 of The Journal is now being prepared, but, owing to the shortage of paper, it is not being included with this issue, as has been the custom in former years. A copy of this index will be sent to any member or subscriber whose request is received prior to January 15, 1919.

There is a possibility that the delegation will not have to sail until the latter part of the week of the Annual Meeting, in which case President Main will be in attendance at least during the opening sessions.

Bulletin on Fuel Saving in House Heating Boilers

The need for saving coal in the domestic sizes is still very urgent, particularly in view of the drop in coal production during the period of influenza, and makes of timely interest a bulletin issued by the Bureau of Mines on Low-Rate Combustion in Fuel Beds of Hand-Fired Furnaces. This is known as Technical Paper No. 139, intended to supplement Technical Paper No. 137, which covers higher rates of combustion, such as burning coal under power-plant and locomotive boilers. Both of these papers are based on the results of actual tests. Those for Paper No. 139 were divided into three groups, according to the method of charging the fuel and of feeding the air under the grate. The tests of the first group were made in a way to be comparable to those of the high rates of combustion. The tests of the second group were made under similar conditions as regards feeding of air, but the fuel was charged in large quantities at long intervals to simulate the feeding of coal in house-heating apparatus. In the third group of tests all access of air through the grate was shut off, the object being to parallel conditions when running with the fire banked and the furnace closed during the night. The pamphlet discusses the results very fully under the conditions of tests outlined.

COMPLIMENTARY DINNER TO AMBROSE SWASEY

THERE was recorded in the last number of THE JOURNAL the gift by Ambrose Swasey, Past-President and Honorary Member of the Society, of an additional $100,000 to the Engineering Foundation. As known to our members, this foundation was established by the United Engineering Society, representing the four founder societies, as the result of an initial gift by Mr. Swasey of $200,000.

In recognition of these splendid gifts to the cause of research, the United Engineering Society on November 14 gave Mr. Swasey a complimentary dinner at the Engineers' Club of New York. There were about 70 guests present, among whom were 22 past-presidents of the Founder Societies, members of the boards of government of the Engineering Foundation and the Founder Societies, members of the Library Board and officers of the Engineers' Club, making one of the most distinguished gatherings of engineers which has ever been brought together.

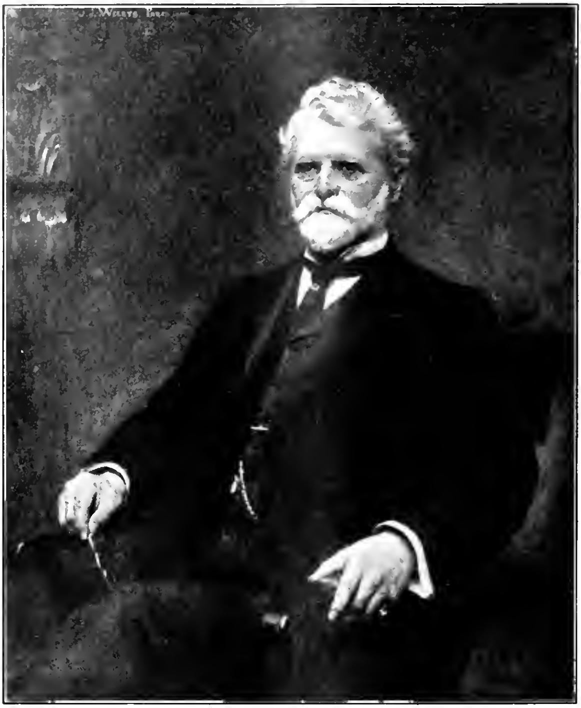
The addresses were by Mr. Swasey's life-long friends, Dr. Robert S. Woodward, President of the Carnegie Institutions of Washington, Dr. Robert W. Hunt, Past-President of this Society, and by the Chairman of the Engineering Foundation, Dr. Michael I. Pupin, with a response by Mr. Swasey. Dr. Woodward spoke in an especially happy vein, stating that he was a silent partner with Mr. Swasey, assisting by advice in the development of the gift.

The desire of Mr. Swasey to contribute so liberally to the cause of research is but a reflection of the spirit and motives which have always entered into his life work in the field of science and engineering. In the manufacture of machine tools of the finest type, the construction of instruments of precision and in the production of astronomical and optical instruments, comprising the mountings for the largest and best known of the world's telescopes, the manufacture of meridian circles, transits, range finders, etc., the results of research and investigation have been constantly required.

His interest in scientific attainments and in instruments of refinement and precision was further shown in a presidential address before the Society upon the subject of Some Refinements of Mechanical Science. In this he reviewed the development of dividing engines, of both the linear and circular types, including the remarkably accurate instrument developed at his own plant for astronomical work, besides other apparatus of a like character.

Appreciation of the need for research is greater now than at any time in the history of industry and the engineering profession and those connected with the industries generally are to be congratulated on having a foundation so thoroughly established for the promotion of scientific investigation in engineering and technology.

Besides his gifts to the Engineering Foundation, Mr. Swasey has given a great deal of pleasure and satisfaction to his friends by presenting to the United Engineering Society earlier in the year a remarkably fine portrait of himself painted by the famous French artist, Jean-Joseph Weerts. A reproduction of this painting is given herewith, taken from a photograph of the original which hangs in the Library of the United Engineering Society. Mr. Swasey sat for this portrait in Paris in 1906.



PORTRAIT OF AMBROSE SWASEY REPRODUCED FROM PAINTING BY WEERTS OF PARIS; PRESENTED BY MR. SWASEY TO THE UNITED ENGINEERING SOCIETY

The artist Weerts received his training in the studio of Cabanel and has exhibited every year in the Salon. While several beautiful paintings of a general character stand to his credit, he has excelled in portraiture through his rare talent in securing perfect resemblance, an abundant of detail and excellent finish.

Meetings of the Screw-Thread Commission

In the November issue of THE JOURNAL on page 972 reference was made to the organization of the National Screw Thread Commission and an abstract was given of the meeting of October 7. On October 21 a second hearing was held in New York and the topics for discussion at this meeting are listed below:

Pipe Threads: (1) As a national standard, is there any objection to the adoption of the American Briggs pipe-thread sizes for both taper and straight pipe threads as accepted by The American Society of Mechanical Engineers? (2) In view of the experiments on the form of pipe threads conducted by the Pennsylvania Railroad in connection with the American Society of Testing Materials which tend to show the desirability of the U. S. Standard form with flat top and bottom 1/8 of the pitch; do you consider it advisable to adopt the U. S. Standard form instead of the present form which specifies a thread depth of 0.8 of the pitch with a resulting flat at the top and bottom of the thread which is quite small? (3) In your shop practice to what extent do you employ gages for checking pipe threads and what do you consider a satisfactory tolerance for ordinary commercial work stated in turns either way from the gaging notch?

Brass Tubing: (1) What is your shop practice in connection with threads cut on various forms of brass tubing? (2) To what extent do you consider it possible to standardize the general practice on the threads used on brass tubing?

Hose Couplings: (1) As a national standard, is there any objection to the adoption of the hose-coupling sizes now known as the National Standard hose couplings in the sizes from 2½ in. to 4½ in. as recommended by the National Fire Protection As-

sociation; Bureau of Standards; American Society of Mechanical Engineers, and other organizations? (2) What is your shop practice in the manufacture of hose-coupling threads on sizes below $2\frac{1}{2}$ in? (3) To what extent do you consider it possible to standardize commercial practice in the manufacture of hose-coupling threads on the sizes below $2\frac{1}{2}$ in?

Acme and Other Special Threads: (1) What is your shop practice in the manufacture of Acme threads and other special threads used in machine construction? (2) To what extent do you consider it possible to standardize the form of thread and pitches used in the manufacture of Acme threads and to standardize other special threads used in machine construction? (3) To what extent do you consider it possible to standardize the general practice with reference to the diameters used for Acme thread pitches?

Instrument Threads: (1) In your shop practice in the manufacture of instruments, to what extent do you use the A.S.M.E. threads; the British Association threads; metric threads; or your own special threads; and to what extent do you consider it possible to standardize commercial practice for this class of work?

Hearings were also conducted in Washington on November 8, in Detroit on November 11 and in Dayton on November 13, of which further mention will be made in an early issue of The Journal.

THE ANNUAL MEETING IS AT HAND

By the time this number of The Journal reaches many of its readers the thirty-ninth Annual Meeting will be under way, with every promise of being one of the most successful of the Society's conventions.

Coming at a time when world peace promises to be an early reality and when engineers will be called upon to lead in the readjustment of industry to peace conditions, this meeting assumes even greater importance than the war conventions at Cincinnati, New York and Worcester which have preceded it. These were the largest, most enthusiastic and most significant meetings ever held by the Society and predicate still greater success for the one that is about to be held.

Among the broader problems to be dealt with during the period of reconstruction is that of labor, or human relations in industry. With rare foresight the Committee on Meetings and Programs planned last spring for an all-day session at the Annual Meeting on the Engineering of Men. This will be the subject of the Keynote Session, which will be addressed by some of the foremost authorities in the country.

In view of the important work of standardization undertaken by the Congressional Screw-Thread Commission, a session will be devoted to Screw Threads and Screw-Thread Gages, with contributions by representatives of the British Engineering Standards Association, the National Physical Laboratory, our own Bureau of Standards, and the Congressional Commission.

At the opening session on Tuesday evening President Main's address will be given—on the Broader Aspects of the Work of the Engineer; and the Secretary is pleased to announce that on the same evening Honorary Memberships will also be conferred on Messrs. Charles M. Schwab and Orville Wright.

Besides the usual business, with reports of Standing and Special Committees, etc., at the first morning session, there will be an important preliminary report by the newly formed Committee on Aims and Organization, with representatives from each of the Sections and from the Society at large.

On Wednesday and Thursday evenings there will be illustrated lectures of the greatest interest on the engineering work of the Army and Navy in the war. A luncheon will be held on Wednesday noon, with an address by George W. Kirchwey on a Message from the Legal Profession.

Besides these features there will be various entertainment features, excursions, luncheons, etc., tea and entertainment for the ladies, and an opportunity for dancing. Members and guests from other cities are cordially invited to join with the New York members in these events.

The following is a list of the papers to be presented, besides which there will be several addresses:

For presentation, Wednesday morning, December 4

Report of Committee on Standardization of Flanges and Pipe Fittings

For presentation, Wednesday afternoon, December 4

The British Engineering Standards Association, C. le Maistre

Work of British Engineering Standards Association on Screw Threads and Limit Gages, Sir Richard Glazebrook

Present Practice in Thread-Gage Making, F. O. Wells

The Measurement of Thread Gages, H. L. Van Keuren

Standards for Large Taper Shanks and Sockets, L. D. Burlingame

Refrigerating-Plant Efficiency, Victor J. Azbe

For presentation, Thursday morning, December 5

Industrial Organization as It Affects Executive and Workers, C. E. Knoeppel

Non-Financial Incentives, R. B. Wolf

For presentation, Thursday afternoon, December 5

Employment of Labor, Dudley R. Kennedy

Labor Dilution as a National Necessity, Frederick A. Waldron

Intensive Training, C. R. Dooley

Properties of Airplane Fabrics, E. D. Walen

Industrial Power Problems, W. F. Uhl

Daylight vs. Sunlight in Sawtooth-Roof Construction, W. S. Brown

Factory Stairs and Stairways, G. L. H. Arnold

The Weights and Measures of Latin America, Frederick A. Halsey

Efficiency and Democracy, H. L. Gantt

For presentation, Friday morning, December 6

The Conservation of Heat Losses from Pipes and Boilers, Glen D. Bagley

Chemical and Physical Control of Boiler Operation and the Application of Simple Formulae for Estimating the Heat-Loss Items, etc., E. A. Uehling

The Cooling Losses in Internal-Combustion Engines as Affecting Design, C. A. Norman

Discussion of Certain Problems in Regard to Marine Diesel Oil Engines, J. W. Anderson

Valves and Fittings for High Hydraulic Pressures, W. W. Gaylord

The Relative Corrosion of Alloys, R. B. Fehr

The Relative Corrosion of Cast-Iron, Wrought-Iron and Steel Pipe in House-Drainage Systems, Wm. P. Gerhard

Determination of Stresses in Wire Rope as Applied to Modern Engineering Problems, J. F. Howe

Mechanical Features of the Vertical-Lift Bridge, Horatio P. Van Cleve

A STUDY OF ENGINEERING EDUCATION

REPORT BY DR. CHARLES RIBORG MANN[1]

IN 1907 the Society for the Promotion of Engineering Education invited the American Society of Civil Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Chemical Society to join it in the formation of a joint committee to examine into all the branches of engineering education. The next year the Carnegie Foundation for the Advancement of Teaching was invited to appoint delegates to the committee, and subsequently the Carnegie Foundation undertook to carry out the work on a large scale, and selected Dr. Charles R. Mann to make a careful investigation and report. The committee has kept in close association with Dr. Mann during the progress of the work.

Dr. Mann's researches have been published by the Carnegie Foundation in a special bulletin of 138 pages. They have also been published rather extensively in the September issue of the *Bulletin* of the Society for the Promotion of Engineering Education. Both accounts have been consulted in preparing this abstract.

Dr. Mann's report is divided into three parts. The first part states what present practices and conditions are, and describes the situation that needs analysis. It treats of the development of the engineering schools in the United States, their early history and the aims and curricula of the old schools. Because of the failure of the engineer to recognize that engineers could be trained in school, the engineering schools had to overcome many obstacles before they were acknowledged by the profession. Up to that time engineers had been merely trained by the apprenticeship method.

This part also deals with the changes of curricula from the beginning to the present time, and discusses the methods of administration in engineering schools, faculty control, student elimination and progress. It then takes up types of instruction in engineering schools, and indicates briefly some of the common practices in teaching the standard or fundamental subjects such as physics, mathematics, chemistry and English.

The second part discusses the problems of engineering education.

The development of entrance requirements has been away from the control of individual judgment and toward a system of committee control, as is evidenced by the creation of the College Entrance Examination Board. In order to indicate how entrance tests could be developed and what reliance could be placed on them, a series of experiments were made for the Carnegie Foundation by Professor Thorndike, of Columbia University.

Attention is directed to the fact that the current practice in making curricula is for the faculty to discuss only the time to be allotted to each subject, and not the degree of skill an engineer is expected to acquire in that particular subject.

In regard to the question of testing and grading, it is pointed out that an objective test, in which every one must agree to its finding, is a real measure of achievement; whereas the current methods are subject to the fallacies of individual judgment, because every department sets its own examinations and passes its own judgment.

Special consideration is given to the problem of shopwork. The original type of shopwork was merely to send the boy out to observe what was going on in shops. Later, the idea was to make the boys build something salable. At present the common plan in most of the schools is to teach the physical manipulations required in the fundamental shop operations without insisting on the acquisition of any construction experience.

There is also the type, developed at the University of Cincinnati, where the boys spend half of their time in a real shop, doing production work for pay, and the other half in school, discussing the problems which they have discovered in the shop.

No judgment is passed on the relative merits of these plans, but the question is raised as to whether the scheme where the students spend part of their time in a real industrial plant, there meeting the real problems of industry and thence carrying them back to the school for discussion, does not offer a clew to a fruitful solution of the shopwork problem.

The third part of the report suggests solutions of the problems that have been discussed.

It is recommended that the number of credit hours per week be less than eighteen, preferably sixteen, in order that the students may do their work more thoroughly. Also, in constructing a curriculum, it is suggested that the number of simultaneous courses be limited to four or five at the outside.

The adequate provision in the first two years for contact with real engineering projects and the interrelation between the concrete and the abstract are considered as essential in all engineering curricula.

The report advocates that the first step in framing a course of study is to define the common basis of all engineering as clearly as possible; that is, to make a list of all the facts, principles and processes that are essential elements in the equipment of every engineer. Theoretically this is the plan on which present curricula are founded, for they all have a common core made up of three distinct parts, namely, science (mathematics, chemistry, physics and mechanics), mechanic arts (drawing and shop), and the humanities (English and foreign languages). All of this common core is usually explicitly required of every student, no matter what specialty he may choose.

In the current organization of the common core of all engineering, however, the report recognizes no inherent or intrinsic relationships among the three categories under which the classification is made, and indicates that in designing curricula, the fundamental aim of engineering should be kept in mind. There must be actual participation in real industrial work; there should be engineering laboratory work, including drawing and descriptive geometry; mathematics and science should be developed systematically in logical order so as to furnish the backbone of the course; and the instruction in the humanistic studies should be presented with a view to develop skill in expression, interest in literature, and an appreciation of the human relation involved in engineering.

Throughout the entire course a great deal of attention must be paid to the testing and sorting of the men. Testing and sorting processes were in a very vague state a year or two ago. But an enormous amount of experience is being developed and collected at the present time by the efforts of the War Department to test and sort men for the Army mobilization. The Department now has psychological laboratories for testing all the men in two of the camps. They have personnel officers in all of the camps, and the work is making rapid progress. An enormous amount of information as to the meaning of these tests and their validity in sorting out ability is being gathered and digested and trade tests are being devised to pick out specific ability for certain lines. The results of their investigations as to valid methods of using objective tests will be of importance in selecting students for admission to engineering schools and in sorting young men during the first year or two of their course, so as to decide whether a boy ought to go into the civil engineering or some subhead under civil engineering, or into mechanical or electrical engineering. In other words, the experiences with the students in their common work that extends over two or three years should be utilized not only to train the man's ability to know and do things, but also as a means of vocational guide to select men and steer them, in the latter part of their course, into the special lines of work for which they are fitted. So the latter part of the course will be made up of large groups of specialties. Those who have been selected by the first two or three years' work as qualified for civil engineering will be put in a group where for the next year or so they will deal first with all the materials of civil engineering not included in the first two years, but which are essential to all the sub-specialties of civil engineering. Then they will proceed from that into some particular specialty.

The report recognizes that the teacher is the crux of the situation, and that the present organization of universities is not well qualified to encourage teachers to experiment and undertake

[1] Professor of Education and Director of Educational Research, Massachusetts Institute of Technology; Director of Committee on Education and Special Training, War Department.

the sort of investigation that is going to be necessary in order to put the suggested plan into operation. Hence it recommends that an organization be made at the school for the purpose of studying the teaching problem, and the school and faculty recognize at the start that it is some business of the professor of physics what the professor of mathematics is doing; and it is some business of the professor of electrical engineering what the professor of chemistry is doing. With such an organization in existence, a spirit of coöperation will be developed among the faculty. The professor of mathematics, for example, if he goes into it in the right spirit, instead of feeling that his interests have been sorely trampled upon when the professor of physics or engineering presumes to tell him what they want done, will find his work in mathematics has become enormously more inspiring to him and to the students. It will engender good feeling of the very best sort and result in a release of creative energy among the whole faculty. Thus conditions will be developed at the schools that will make the teachers want to study their problems together, instead of those which discourage the undertaking of anything that is not according to an established practice.

The system in vogue in the universities to make research work and the publication of the results of research the measure of success and the criterion of promotion for teachers, is pertinently criticized in the report. In this connection it says:

It is unquestionably true that research, as at present treated, does interfere seriously with teaching. Hundreds of college instructors whose interests lie in the human problems of education, rather than in the material problems of natural science, are now being diverted from a study of the teaching problem and induced to undertake research because academic promotion so obviously depends on the latter. Many a young man with promise of making an excellent teacher is sidetracked by the requirements for the Ph.D. degree and becomes instead, a mediocre researcher. Yet though much that is done under the name of research is but pseudo-research, the university is clearly right in its position that the spirit of investigation is an essential factor of university life.

The difficulty does not lie in research itself, but in the limitations that still cling to the common interpretation of it. Because research has been developed in the field of natural science and has wrought such marvels there, its activities have unconsciously been thought of as restricted to the problems of the material world. Because the technique of research and the units and methods of measurement have been so perfected in the domain of natural science that great accuracy and definiteness of conclusion are now possible, the early struggles for objectively defined standards and scales have been forgotten. Hence it seems to many grotesque to talk about research in education and the impersonal measurement of the vaguely defined and elusive qualities of human beings. The fact that such measurements have as yet been rather crude and inconclusive is no reason against trying to improve them, especially now when the greatest need of education is a technique and a terminology that will make the results of experiments in teaching intelligible to every one. . . .

If university trustees, presidents, and faculties will unite in insisting on a scientific study of their educational work, they will create the conditions needed to release teaching power in the engineering schools. The professors who have teaching interest and ability will welcome the opportunity to win recognition in work that arouses their enthusiasm and stirs their imagination to creative effort just as the professors who are interested in natural science have responded to the opportunity to promote research. This should not result in a diminution of output in research, but in a decided increase, because it tends to give each man the work he is best fitted to do, and therefore leads ultimately to maximum efficiency.

An understanding of the spirit of Dr. Mann's study and the line of reasoning which has led to his conclusions is obtained from the part of his report entitled The Professional Engineer. He remarks in explanation of the purpose of his work:

The statement that individuality counts for as much as learning for the engineer, just as it does for the lawyer or the physician, seems like a veritable platitude. Yet because the engineering schools have always made it their chief aim to impart the technical information needed in industrial production, and because both scientific knowledge and industrial practice have grown so rapidly, the attention of technical schools has been focused chiefly on keeping up to date in science and practice. The university emphasis on research in natural science has also tended to magnify the importance of technique and to minimize the importance of personality; until curricula have become so congested with specialized courses that students generally regard literature and sociology as unnecessary chores, to be endured rather than enjoyed. Therefore it seemed necessary to consider the question whether this emphasis on technique is producing a new and higher type of engineer, or whether the engineering profession still stakes its faith on the fundamental thesis that personal character is, after all, the real foundation for achievement.

To arrive at the requirements of the engineering profession, circular letters were sent to engineers throughout the country, asking them what they deemed the most important factors in determining probable success or failure in engineering. The result of their replies, in which personal qualities were numbered seven times as frequently as knowledge of engineering science and the technique of practice, was sent to the thirty thousand members of the four large engineering societies, and each was asked to number six groups of qualities headed respectively character, judgment, efficiency, understanding of men, knowledge, and technique, in the order of importance which he gave them in judging the reasons for engineering success and in sizing up young men for employment and promotion. Their votes placed the character group at the head of the list by a majority of 94.5 per cent, while technique was voted at the bottom by an equally decisive majority.

Thus it appears that there is a keen appreciation of the importance of the personality of the engineer. Dr. Mann thinks that recent events have brought out that need still more clearly.

Further in this part he summarizes the situation as follows:

The ultimate aim of engineering education has always been and still is more intelligent industrial production. Technical schools were founded when industrial evolution had progressed so far as to create a pressing demand for men who knew how to utilize the new and rapidly expanding knowledge of natural science to increase and improve production. Science was then little taught in high schools and colleges, so that both the public and the manufacturers were ignorant of it. Under these conditions the obvious need was for scientific enlightenment; and this the engineering schools were organized to supply . . .

The schools . . . . have thereby contributed enormously to the achievement of two striking results; namely, the extension of science instruction into the school system generally, and the development of public recognition of engineering as a profession, coördinate with theology, medicine, and law. At the present day an encouraging fraction of the people are reasonably intelligent in science, the worker in applied science has become socially respectable, and there has been developed a large conception of the engineering profession. Meanwhile the methods of dealing with the material problems of industry in a scientific way have been in a measure established, while the more intricate problems of organizing and managing men are rapidly pressing forward and demanding engineering treatment.

The net result is that the curricula and methods of instruction that were devised to supply the intellectual element in production by imparting knowledge of natural science must be recognized to meet the new industrial demand for engineering administrators and the larger professional demand for men of strong personality. The general plan of the proposed reorganization is based upon an analysis of engineering practice into its three essential factors; namely, knowledge of engineering science, skill in technique of application, and judgment in the appraisement of values and costs. In every engineering project the overlapping claims of these three essential factors must be harmonized with respect to the two fundamental elements of production, namely, materials and men. Surely every engineer should have some conception of the present conditions and problems in at least the general aspects of all these essential factors and elements. If this be granted, it is easy for any school to discover where its curriculum is overloaded and where it is deficient.

This analysis also indicates how the present organization of school work can be modified so as to furnish a more vital training for professional engineers. Thus, with regard to materials, the schools do give careful instruction in the laws of physical science and in the properties and uses of materials. Students are taught the relative strengths of substances in the materials laboratory, kinematics teaches the principles of gearing, the shapes of gear teeth are worked out in the drawing room, the chemical properties are taught in chemistry, mechanics deals with the forces required to overcome inertia, machine work is relegated to the shop, and so on. But seldom is all this information coördinated in a single practical problem, such as determining whether mild steel, nickel steel, or phosphor bronze is the best thing to use in making a particular gear wheel; nor is the student ever asked to judge what combination is likely to produce the most valuable result for the price. Yet this balancing of value and cost is the controlling factor in all intelligent production.

. . . . An adequate treatment of the first element in production involves not only a scientific presentation of the laws of nature and the properties of materials, but also an estimation of the values and costs from both the material and the human points of view. The chasm between the school and practical life is due largely to a failure to appreciate this fact. The introduction of the study of values and costs in all their phases is the most direct method by which the schools can bridge this chasm. Such study is also one of the most potent means of liberating creative energy and of developing the spirit of investigation.

REPORTS OF STANDING COMMITTEES OF ADMINISTRATION

THE reports of Standing Committees of Administration[1] of The American Society of Mechanical Engineers will be presented at the forthcoming Annual Meeting as an appendix to the Annual Report of the President of the Society's activities for the year. The reports are published below.

Report of Finance Committee

The Finance Committee reports that the income of the Society for the year ending September 30, 1918, was $240,086.70. After reserving $15,000.00 for obligations undertaken but not yet completed, the total expenditures chargeable to income were $223,701.21, leaving an excess of income over expenditures of $16,385.49.

Based on a membership of 8720, the average of the total membership on October 1, 1917, and that on October 1, 1918, the average income of the Society per member for the fiscal year just closed is tabulated below. The corresponding income for the preceding year is included for comparison.

AVERAGE INCOME PER MEMBER

	1916-17.	1917-18.
Membership Dues	$14.57	$14.06
Sales—Gross Receipts	1.90	1.61
Advertising	8.42	9.31
Interest and Discount	.62	.50
Initiation Fees (one-half)	.90	1.02
	$26.41	$26.50

One-half of the initiation fees are put into reserve each year, so that the figures given above represent that portion.

Based on the same average membership, the expenditures of the Society per member for the fiscal year just closed are also given below, together with the corresponding expenditures for the previous year for comparison.

AVERAGE EXPENDITURES PER MEMBER

		1916-17.		1917-18.
Meetings, Annual and Spring		$1.39		$1.41
Publications:				
Journal	$9.01		$7.29	
Condensed Catalogues			2.19	
Transactions	1.75		2.22	
Year Book	.68		.79	
		11.44		12.49
Membership and Increase of Membership		1.37		2.09
Office Administration		2.85		3.00
Upkeep of Headquarters		.32		.32
Employment Bulletin		.27		.33
Government Employment Work		.19		.20
United Engineering Society:				
Assessment to U. E. S.	.85		.55	
Library	.53		.46	
Engineering Council	—		.42	
		1.38		1.43
Local Sections		1.06		1.59
Council Contingencies, Mileage		.56		.52
Student Branches		.16		.07
Cost of Publications, Pamphlets, etc.		1.08		.99
Engineering Committees:				
Standardization, Research, Boiler Code, Screw Threads, etc.		.45		.93
Other Activities		.23		.28
Total		$22.75		$25.65
Additions to Building.				

(Journal and Condensed Catalogues together: $9.01 in 1916-17.)

The Budget Appropriation recommended by this Committee and approved by the Council for the year 1918-1919 is as follows, being 87 per cent of the estimated income:

Finance Committee:		
Office Administration	$26,100	
Occupancy of Building and Engineering Council	8,800	
Library	4,800	
		$39,700
Membership Committee		5,000
Council:		
Contingencies	3,500	
Committees not otherwise provided for	9,200	
Mileage	2,500	
Employment Bulletin	3,500	
		18,700
Sections Committee		13,500
Increase of Membership Committee		10,000
House Committee		5,650
Meetings Committee		12,750
Publication Committee		117,000
Research Committee		2,000
Students' Committee		1,000
Junior and Student Prizes Committee		75
Sales Expenditures		9,500
John Fritz Medal Board of Award		75
Engineering Resources Committee		800
Public Relations Committee		500
Total		$236,250

In addition, $10,000 was aproved by the Council, to be taken from surplus, for initiation of the Engineering Index.

The estimated income for the year 1918-19 is $270,730.

Appended will be found reports of the accounts of the Society as shown in the books for the fiscal year ending September 30, 1918.

DEATH OF MR. ROBERT M. DIXON

At a special meeting of the Finance Committee of The American Society of Mechanical Engineers held November 7, 1918, the following resolutions were adopted on the recent death of Mr. Robert M. Dixon, an honored member of the Society for the past thirty years and Chairman of the Finance Committee more than eight years:

Whereas, it has pleased an Allwise Providence to remove from us our fellow member and leader, therefore be it

Resolved, That in the death of Mr. Robert M. Dixon, for ten years a member of the Finance Committee and for more than eight years its Chairman, the Society has lost one of its most valuable members and the Finance Committee a leader whose wise counsels and mature judgment contributed in a most conspicuous manner to the present sound financial condition of our Society, which is in itself a most flattering tribute to the financial and executive ability of the Engineer, the Citizen and lovable companion whose loss we mourn.

And be it further Resolved, That a copy of these resolutions be spread upon the minutes of this meeting, and a copy properly amplified with historical data be engrossed for presentation to Mr. Dixon's family, and for publication in THE JOURNAL and TRANSACTIONS of the Society.

Respectfully submitted,

GEORGE M. FORREST, *Chairman*,
THEO. STEBBINS,
ALFRED FORSTALL,
W. E. SYMONS,
Finance Committee.

REPORT OF ACCOUNTANTS

FINANCE COMMITTEE,
THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

DEAR SIRS:

In accordance with your instructions, we have examined the books and accounts of The American Society of Mechanical Engineera for the twelve months ended September 30, 1918.

The results of this examination are set forth in the three exhibits attached hereto, as follows:

Exhibit A Balance Sheet, September 30, 1918.
Exhibit B Income and Expenses for the twelve months ended September 30, 1918.
Exhibit C Receipts and Disbursements for the twelve months ended September 30, 1918.

We certify that, in our opinion, the accompanying Balance Sheet is a true exhibit of its financial condition as of September 30, 1918, and that the attached statements of Income and Expenses, and Receipts and Disbursements, are correct.

Respectfully submitted,

(Signed) WM. J. STRUSS & Co.,
Certified Public Accountants.

EXHIBIT A

BALANCE SHEET, SEPTEMBER 30, 1918.

ASSETS

Equity in Society's Building (No. 25 to 33 West 39th Street)	$365,846.62	
Equity in one-third of Cost of Land (No. 25 to 33 West 39th Street)	180,000	
		$545,846.62
Library Books	13,000.00	
Furniture and Fixtures	5,000.00

Report of Committee on Meetings and Program

As the financial year of the Society does not correspond with the calendar year, it becomes necessary for this Committee to consider two general meetings in retrospect and one in prospect, yet of the former, only one was planned for by the Committee as now constituted.

The Annual Meeting held in December 1917 was the largest in the history of the Society in point of registration. The total number was 1965, of which 1115 were members and 850 guests. The number of members exceeded the registration at the Annual Meeting of 1915 by 88.

Because of the unsettled conditions due to the war activities of so many of our members, the 1917 Annual Meeting was given over to a larger number of addresses than usual and to fewer professional papers. However, the established practice of holding a keynote session was followed, the topic being Service of the Engineer to the Public in Times of National Crises.

The Spring Meeting of 1917 held in Cincinnati broke all previous Spring-Meeting records in regard to attendance, but the high record was again surpassed at the Worcester meeting of this year, the total registration being 986, of which number 472 were members and 511 guests. These numbers compare with 868, 410 and 458 respectively, the record at Cincinnati.

These increasing numbers in attendance at our meetings are significant of the broader field of activity that our Society is entering.

The situation brought about by the few papers offered for the Annual Meeting of 1917 existed at the time of the Spring Meeting of this year. But during the past few months a decided change has taken place in this particular. At the September meeting of your Committee not only was there a prospect of many more professional papers than can be presented in December, but nearly enough papers were ready for final approval at that time. It is possible that this change is an evidence of the stimulating effect of the war, which we are told has had a remarkable influence upon British engineering literature.

Some Features of the 39th Annual Meeting

Four features of the forthcoming December meeting deserve mention. A year ago an innovation was introduced into the program by providing for a luncheon at which time an address was given by Professor Dexter S. Kimball. A similar luncheon is planned for the forthcoming Annual Meeting, and at the request of the newly appointed Committee on Aims and Organization, that Committee has been given the privilege of providing the speaker and selecting the topic of his address.

The keynote session will have for its general theme Engineering of Man Power.

A joint session with the Society of Refrigerating Engineers has been scheduled. A part of the professional papers will be supplied by each society. Your Committee has been very willing to enter into this arrangement, which is in keeping with the Society's general policy

[1] Note: The item of total expenses includes $15,000 not yet paid, to complete work already in process and chargeable to this year's activities.

in maintaining close coöperation with other engineering organizations.

The fourth feature for the Annual Meeting that should be mentioned here is the giving of a prominent place on the program to the Committee on Aims and Organization, namely, that period of the session on Wednesday morning immediately following the regular business meeting of the Society.

WORK OF THE SUB-COMMITTEES

The work of the sub-committees of the Committee on Meetings and Program has, in the main, been exceedingly satisfactory. Without seeming to single out any one of these before another, it is a pleasure to acknowledge the unbroken record of successful sessions planned for by the Textile Sub-Committee under the chairmanship of Mr. Charles T. Plunkett.

The activities of the Sub-Committee on Protection of Industrial Workers having assumed more of the character of a special committee, the Committee recommended to the Council that the status of this committee be changed to that of a special committee. The recommendation was accepted.

The Committee favors a policy of appointing temporary sub-committees to investigate specific matters and assist in preparing special parts of the program of the meetings. However, it has not had opportunity to put this plan into full effect.

ACKNOWLEDGMENT

To an increasing degree during the past year the Committee has submitted professional papers to members of the Society who are especially conversant with the topics discussed, in order to have their opinions when the papers were considered for final disposition. It is a pleasure to acknowledge the uniform cordial coöperation that all of these requests for assistance and advice have evoked.

Respectfully submitted,

L. P. ALFORD, *Chairman*,
JOHN W. UPP,
DEXTER S. KIMBALL,
A. L. DE LEEUW,
WILLIAM G. STARKWEATHER,
Meetings and Program Committee.

Report of Publication and Papers Committee

The chief development of the Society's publications during the past year has been the establishment in THE JOURNAL of a comprehensive indexing of engineering periodical literature with particular reference to mechanical engineering subjects. This feature is one that has been consistently advocated by the Committee for many years and in fact was first proposed by the original committee appointed by the Council to report upon the establishment of THE JOURNAL. The actual accomplishment of the index feature has only awaited the time when it was felt by the Council that the Society was in a position to undertake it.

Coincident with this development, there has been under consideration an offer by the publisher of *Industrial Management* to sell its long-established Engineering Index, the purchase of which the Publication Committee now recomends to the Council. It is believed by the Committee that the indexing of engineering articles can best be accomplished by a professional organization, such as ours, through the facilities afforded by our magnificent library, which regularly receives over 1000 periodicals from all parts of the world. The purchase of the Index would bring to THE JOURNAL the prestige, name and other rights and privileges of what has been regarded as the leading index in the field, and establish this as a Society activity on a secure and non-competitive basis.

The addition of the index feature to THE JOURNAL brings this publication to as large a size as can advantageously be handled in monthly issues. Further increases to make THE JOURNAL more valuable to the profession will necessitate more frequent publication. Such development, however, must obviously be left until industrial conditions return to normal.

In compliance with the wishes of the War Industries Board that the tonnage of paper required for periodicals be curtailed, THE JOURNAL will for the present use a larger type page with more closely spaced type.

The annual volume of Transactions has been issued as usual with no material change, except that the subject matter has been influenced by the engineering work which so many of our members are doing in connection with the war.

There has been a considerable gain in the size and comprehensiveness of the annual volume of Condensed Catalogues for the current year. Four hundred and fifteen firms, including a majority of the leading manufacturers in their respective lines, are represented in its pages of catalogue data. The directory section has been extended and improved and to the mechanical engineering data section there has been added a subject list of Transactions papers, beginning with the first volume issued in 1880. The compiling and printing of this list was considered desirable, because the Society has not yet been able to issue the comprehensive index to Transactions which the Committee has several times recommended and for which the preparation of the index cards was completed two years ago. It is strongly urged by the Committee that this index be issued as soon as conditions allow.

At the last Spring Meeting, certain changes in the Constitution of the Society were effected, one of which designates this Committee as the "Publication and Papers Committee." In this connection, it is interesting to note that the Publication Committee was originally responsible for the approval of the papers which were to be presented at the Society's meetings, and printed in its Transactions. In 1904, the Committee on Meetings was organized to relieve the Publication Committee of certain of its burdens in respect to meetings, and since then the main function of the Publication Committee has been to pass upon papers referred to it by the Committee on Meetings and more lately also by the Local Sections Committees for use in the Society's publications. The Publication Committee has taken no initiative in procuring papers.

The obvious intent of the constitutional change is to express the desirability of the Publication and Papers Committee taking up the solicitation of papers and contributions for the publications. The Committee respectfully requests that By-Laws be formulated with respect to this function and expressing a clear policy for the handling of papers both for general and Sections meetings and for publications.

The past year has been most successful financially, the gross income from advertising having exceeded $81,000. The financial statement covering the Committee's activities will be found in the report of the Finance Committee.

Respectfully submitted,

GEORGE A. ORROK, *Chairman*,
J. W. ROE,
H. H. ESSELSTYN,
GEORGE J. FORAN,
RALPH E. FLANDERS,
Publication Committee.

Report of the Membership Committee

The Membership Committee held twenty-four meetings during the year 1917-1918, as against nine during fiscal year 1916-17.

The number of applications considered in the transaction of its work and a summary showing the action taken follow:

Applications pending October 1, 1917	863
Applications received during the fiscal year	1901
Total	2764
The following action was taken on these applications:	
Recommended for membership	1769
Recommended for membership (special cases)	36
Deferred indefinitely	20
Deferred	42
Denied promotion	13
Remission	8
In regular course of procedure	844
Foreign deferred for period of war	32
Total	2764
Reinstatements and reconsiderations pending	30

Those recommended for membership were divided into the following grades:

Members	486
Promotion to Member	60
Associates	104
Promotion to Associate	2
Associate-Members	575
Promotion to Associate-Member	64
Juniors	478
Total	1769

The Membership Committee has been most careful in the scrutiny of applications and no names of candidates have been recommended to the Council unless they are citizens of the United States or of one of the Allies. Action on application from foreigners has been deferred until the conclusion of hostilities.

Respectfully submitted,

HOSEA WEBSTER, *Chairman*,
S. D. COLLETT,
FREDERICK A. WALDRON,
W. S. TIMMIS,
R. F. JACOBUS,
Membership Committee.

Report of Committee on Local Sections

At the Spring Meeting of the Society in Worcester, May, 1918, a Constitutional Amendment was passed which changed the status of the Committee on Local Sections from a Special Committee to a Standing Committee of Administration and to one of the six Fundamental Committees of the Organization of the Society.

Your Committee has held the following meetings during the year:

Date	Place
October 11, 1917	Philadelphia
November 28, 1917	Philadelphia
January 8, 1918	New York
February 11, 1918	New York
March 12, 1918	New York
April 15, 1918	New York
May 13, 1918	New York
July 18, 1918	New York
August 28, 1918	Philadelphia

By-Laws Governing Sections

At its October meeting the Committee reviewed the final revision of the proposed By-Laws governing Local Sections and recommended them to the Council for adoption. They were subsequently adopted and now appear as B-48 and B-49 in the By-Laws.

These By-Laws have since been published in The Journal and the following Sections have now adopted constitutions and by-laws in conformity with them: New York, Indianapolis, Minnesota and Birmingham.

Sections Meetings

During the active season, upwards of 120 meetings were held by the various Local Sections. At a large proportion of these the speakers discussed subjects of interest in the winning of the war.

Finances

The Committee on Local Sections was apportioned a sum of $10,750 for its year's expenses, and this the Council augmented in May 1918 by an additional grant of $3,500. The total expenditures for the year amount to $13,887.51.

New Sections

At its October 1917 meeting your Committee received a petition for the establishment of a section for the State of Connecticut with branches at Bridgeport, Hartford, Meriden, New Haven and Waterbury, the New Haven Section being merged in the new State Section and becoming a branch of it, a type of Section developed in coöperation between the Connecticut members and your Committee. The petition was referred to the Council, which approved it.

At its August 1918 meeting your Committee received a petition from Cleveland, Ohio, and this was referred to the Council, which approved it.

At this time local Sections are in process of formation, notably at Pittsburgh, Washington, etc.

Your Committee is continually endeavoring to carry the Local Sections idea into territories which are strong in membership and in activities, and with that object in view is watching its opportunity to spread the gospel of organization in all centers of the country not now included in the already organized Local Sections of the Society.

Coöperation of Sections Committee with Other Committees

In coöperation with the Publications and Papers Committee of the Society your Committee recommended to the Local Executive Committees the appointment of Local Papers Committees. The purpose of these committees is to secure papers for presentation at the meetings of the sections and for forwarding to the Publication and Papers Committee for possible publication in The Journal and for presentation at General Meetings and inclusion in Transactions.

Similarly in coöperation with the Research Committee, your Committee recommended to the Local Executive Committee appointment of sub-committees on Research to ascertain what researches were being carried on or contemplated in the industrial laboratories and in the institutional laboratories in the territory of the Sections.

To date a number of the Sections have appointed sub-committees for both these purposes.

In coöperation with the Membership Committee your Committee is considering ways and means of fostering relations with local societies by means of some plan of joint membership in the National Society and the Local Society. The petition received from the Cleveland Section especially asked this Society to see what could be done to provide such joint memberships, and in accepting this petition the Council obligated itself to consider a practical plan.

In coöperation with the Meetings Committee your Committee arranged for a Session at the Annual Meeting in December, 1917, to be conducted by the Committee on Local Sections. Unfortunately, however, the program of the meeting was so full that very little time could be given to this innovation and it resolved itself into a conference of the Local Sections delegates.

Visits by the Committee and by Officers to the Sections

Beginning October 21, 1917, your Committee visited the Sections at St. Louis, Milwaukee, Chicago and Detroit. The November, 1917, meeting of the Committee was followed by a visit to the Philadelphia Section. An invitation to visit Birmingham was received with thanks and the Committee hopes to take advantage of this within the near future.

It was suggested that it would be well to develop a scheme to take care of visits by officers to the Sections by arranging visits to those Sections located in the part of the country in which the officers reside.

Nominating Committee

In accordance with a suggestion received from President Main, your Committee had a report prepared on the various methods in vogue with other engineering societies of selecting nominees for elective offices, and it devised a plan of placing the selection of the Nominating Committee into the hands of the membership by having it consist of delegates elected by the Sections. This plan was outlined in a report submitted to you by your Committee. The Council referred this matter to the Committee on Constitution and By-Laws, which proposed an amendment to the Constitution so as to provide for the election of said Nominating Committee by the Society membership in place of the present practice, leaving the formulation of all details in connection with this election to the by-laws which it will submit presently to provide for the selection of the Nominating Committee through the machinery of the Sections.

Conferences of Delegates

An important conference of delegates of the Sections was held in New York, December, 1917, in connection with the Annual Meeting, and this was reported in full in the January 1918 issue of The Journal.

Delegates were present from Atlanta, Baltimore, Birmingham, Boston, Buffalo, Chicago, Cincinnati, Connecticut, Erie, Indianapolis, Milwaukee, Minnesota, New Orleans, New York, Philadelphia, Providence, St. Louis, San Francisco and Worcester.

A conference of delegates was also held in connection with the Spring Meeting at Worcester, June, 1918, and reported in the July Journal.

Joint Meetings

During the Summer plans were laid to hold a joint meeting of the Mid-Western Sections in the Fall in some Mid-Western city. In coöperation with the several Local Committees of these Sections the meeting was assigned to Indianapolis and the date fixed as October 25 and 26. The Council decided to meet in Indianapolis at the same time also and at the moment of writing this report the program of said joint meeting is almost completed.[1]

Your Committee hopes that this will prove to be the inauguration of a series of joint Local Section meetings.

Coöperation with Sections of Other Societies and with Local Societies

In San Francisco there has been formed the Joint Council of Sections of the National Societies and the San Francisco Section of our Society participated in this movement. The purposes of the new organiation have been published in the technical press.

In Cleveland our new Section has been formed as the Mechanical Section of the Cleveland Engineering Society. This opens up a new field of coöperation between our Societies and local organizations and we look forward with open but conservative minds to the development of the Cleveland plan.

In many of the centers we have continued our coöperative plan as before. For example, in New Orleans we have coöperated effectively with the Louisiana Society; in Philadelphia we have continued our plan of coöperation with the Engineers' Club; in Chicago several joint meetings have been held under the auspices of the Western Society of Engineers, etc.

War Industries Readjustment Committee

President Main utilized the machinery of the Local Sections organization in appointing representatives of the Society's Committee on Readjustment of War Industries to coöperate with the Regional Committees of the Resources and Conversion Section of the War Industries Board. This Committee is issuing its own report.

Acknowledgment

The Committee desires to express its sincere appreciation of the coöperation of all the Local Committees and recommends that the thanks of the Council be extended to them for their efforts in furthering this important activity of the Society.

We also desire to record our special appreciation of the untiring energy and help which the Society's staff has at all times given to the Sections and our Committee.

Since the formation of our Committee four years ago, Mr. Ernest Hartford has acted as its Secretary and most acceptable have been his services; although we regret his withdrawal from these duties, we are

[1] The meeting was later postponed indefinitely on account of the epidemic of Spanish influenza.

glad that our government will have the advantage of his efficient help.

Respectfully submitted,

D. ROBERT YARNALL, *Chairman*,
LOUIS C. MARBURG,
WALTER RAUTENSTRAUCH,
CHAS. RUSS RICHARDS,
H. B. SARGENT,
Local Sections Committee.

Report of the Committee on Constitution and By-Laws

The Committee records with sincere regret the death on May 14, 1918, of its Chairman.

At its meeting on May 21 the Committee approved the following resolution:

> The Committee on Constitution and By-Laws of the American Society of Mechanical Engineers in parting with its Chairman, Frederick Remsen Hutton, realizes the great loss which it has sustained.
>
> The Committee will greatly miss his wise counsel, his broad vision, his high ideals, his genial bearing and friendship.
>
> The Committee desires to extend to his wife and family its very sincere sympathy in their great affliction.

The Council, at its meeting on October 12, 1917, referred to this Committee the question of the remission of the dues of members who entered the service of the United States for the war with Germany and also the question of the remission of the dues of persons who had been members of the Society for many years, with the view of amending By-Law 16.

The Committee, after careful consideration of the question, presented the following as a substitute for By-Law 16 at the meeting of the Council on November 16, 1917:

> B 16a. The Council may in its discretion restore to membership any person [illegible]ed from the rolls for non-payment of dues, or otherwise, u[illegible]ch terms and conditions as it may at the time deem best for [illegible] interests of the Society.
>
> B 16b. The Council may in its discretion remit the dues of any member of the Society in any grade who is engaged in military or other patriotic service of the United States during the continuance of the war conditions and for a period thereafter.
>
> B 16c. The Council shall permanently exempt from dues any member of the Society who has paid dues for thirty-five years or who shall have reached the age of seventy years after having paid dues for thirty years.

This substitute was approved by the Council at its meeting on January 18, 1918, and went into immediate effect.

At the same meeting the Council approved a recommendation of the Membership Committee as follows:

> *Voted*, That the members who have honored the Society by entering the military service of the United States receive all privileges of their membership, and, upon request, may have current dues remitted.

The Council at its meeting on February 15, 1918, referred to this Committee an elaborate report of the Committee on Local Section, under date of February 11, on the Selection of Officers and Appointment of Nominating Committees.

This Committee gave very careful consideration to the whole subject and submitted to the Council at its meeting in Philadelphia on April 23, 1918, proposed amendments to sections 47 and 48 of the Constitution by which the Nominating Committee would be taken out of the list of Committees to be appointed by the President, and proposing a new form of C 48 to read as follows:

> C 48. There shall be one or more Committees to nominate candidates for the elective offices of the Society, as the By-Laws shall provide.

The Committee took the position that the Constitution should only provide for the fundamental establishment of Nominating Committees and that the details of the number of Committees, the number of members on each Committee, their tenure of office and the mode of their election should be provided for in the By-Laws, where they could be changed as conditions changed. The Council did not approve of the recommendation of this Committee and referred the matter back to the Committee.

This Committee again took the whole subject into consideration and submitted a report to the Council at its meeting in Worcester, Mass., on June 4, 1918.

This Committee proposed that C 47 be amended by striking out the words "A Nominating Committee appointed by the President" and amending C 48 so as to read as follows:

Nominating Committees

> C 48. There shall be a Nominating Committee whose duty shall be to select candidates for the elective offices to be filled at each election This Committee shall be elected by the voting membership of the Society.
>
> Other Nominating Committees having the same power may be constituted by the voting membership.
>
> The number of members, the election, organization and procedure of all Nominating Committees shall be as the By-Laws shall provide.

These proposed amendments to C 47 and C 48 were approved at the same meeting by the Council after amending the proposed C 48 by inserting the word "annually" after "elected" in the second sentence.

These proposed amendments as amended by the Council were sent out in printed form to the membership as provided in C 57, by being published in the July issue of THE JOURNAL, page 53. This matter will come up for discussion at the Annual Meeting in December next.

Respectfully submitted,

JESSE M. SMITH, *Chairman*,
IRA H. WOOLSON,
JAMES E. SAGUE,
GEORGE M. BASFORD,
D. ROBERT YARNALL,
Constitution and By-Laws Committee

AMONG THE LOCAL SECTIONS

THE Annual Report of the Committee on Local Sections for the fiscal year ending September 30, 1918, is printed elsewhere in this issue. The report covers the subjects of by-laws, meetings, finances, new Sections, coöperation of Sections Committee with other committees, visits to the sections by officers, the selecting of the Nominating Committee, conferences of delegates, joint meetings, and coöperation with sections of other societies and local societies.

The report discloses that after only four years of operation the Committee on Local Sections has succeeded in establishing its work on the basis of intimate coöperation with the other committees of the Society, which the Committee thinks is just as essential as developing its own field of activities individually.

The relations of the Committee with the proposed Constitution and By-Laws changes are, in the matter of selection of the Nominating Committee, quite a fundamental change in the government of the Society, have been most satisfactory, and the Committee on Local Sections is justly proud in having taken part in the democratization of the Society by placing the power of appointing the regular Nominating Committee in the hands of the voting membership.

Members might be interested to know to just what extent the Committee on Local Sections carries out this plank of committee coöperation in its platform. At each of its meetings (as the annual report shows, frequent meetings were held during the past year) the committee sits down to a regular order of business, of which the following is a schedule:

ORDER OF BUSINESS

1 Reading the minutes of the previous meeting.
2 Statement of condition of finances:
   (a) Main committee
   (b) Local committees
3 Sections' Officers:
   (a) Recording of new officers of local committees
   (b) Confirmation of changes in local committees
4 Actions of Council and committees affecting Local Sections Committee:
   (a) Council
   (b) Meetings and Program Committee
   (c) Publication and Papers Committee (Sections' Sub-Committees on Papers)
   (d) Research Committee (Sections' Sub-Committees on Research)
   (e) Employment Department
   (f) Membership Committee
   (g) Increase of Membership Committee
   (h) Constitution and By-Laws' Committee.
5 Sections' By-Laws, Rules and Records:
   (a) Proposed amendments to By-Laws
   (b) Progress of adoption of By-Laws
   (c) Record books.
6 Report of Sections organization development:
   (a) Important developments in existing Sections centers

(b) Developments in connection with Sections petitions received
(c) Requests for Sections, and developments in centers where Sections are desirable.
7 Sections coöperation with local organizations of other societies and with local societies.
8 Reports and requests from Local Committees.
9 Relations with Publication Committee:
(a) Technical Section of JOURNAL.
(b) Society Affairs Section of JOURNAL. .. ..
10 Deferred Business.
11 New Business.
12 Adjournment.

A glance at this order of business will show that it aims to cover not only the usual duties of such a coöperative committee as the Committee on Local Sections, but also to emphasize that this committee is subject at all times to the direction of the Council, and is but one factor in the organization of the Society.

In other words, the broad plan on which the Committee on Local Sections works is that while there is strength in an organization of committees assigned to definite tasks, the closest intercommittee relations are at the same time necessary for cohesion and for the development of a coördinate will.

The Committee on Local Sections urges all Section executive staffs to place before it their real problems and constructive criticisms; for through such an interchange of ideas are Society and professional unity and progress assured.

Section Meetings

ATLANTA SECTION

The members of the Atlanta Section were entertained at dinner by the Chairman of the Executive Committee of the Section, Mr. Robert Gregg, at the Druid Hills Golf Club, October 17. After the dinner a paper was presented by E. L. Brooks, Associate Member, Am.Soc. M.E., on the subject Uniform Boiler Code.

The speech was followed by a discussion on the advantage of having the A.S.M.E. Boiler Code adopted by the State of Georgia, and a motion was carried instructing the Chair to appoint a committee of four members to draft the proper bill to be presented to the next legislature.

WILLIAM J. NEVILLE,
Secretary.

BIRMINGHAM SECTION

On November 20, its anniversary day, the members of the Birmingham Section met for dinner in the rooms of the Civic Association. The dinner was followed by a general, informal discussion.

JAMES W. MOORE,
Secretary.

BOSTON SECTION

Mr. A. Douglas Wardrop, Managing Editor of *Aerial Age*, delivered a lecture before the members of the Boston Section on Saturday evening, November 9, the subject being his recent trip to France, and experiences on the fighting line.

The Section is now planning a meeting on the timely subject of Reconstruction.

The report of the October 17 meeting given in the last issue of THE JOURNAL was incorrect. The meeting was held on October 29, and the speakers were F. P. Fish of the General Electric Company, who spoke on the Elements of the Labor Problem. Mr. Fish gave a general résumé of the development of the labor situation both in this country and in England during the last few years. He pointed out the strength and also the weakness of the organized labor movement, and suggested ways in which the engineers could coöperate to alleviate some of the weakness.

Mr. W. E. Freeland, of the Winchester Repeating Arms Co., presented a paper entitled Government Activity Toward the Solution of the Labor Problem. He dealt specifically with the Bridgeport case summarizing the work of the National War Labor Board there, and comparing the award made by this Board with the actual rulings of the examiner appointed by the Board.

Mr. Perry described the plan under which the Emergency Fleet Corporation was adjusting labor difficulties by means of shop committees.

WILLIAM G. STARKWEATHER,
Secretary.

BUFFALO SECTION

The A.S.M.E. Section of the Engineering Society of Buffalo conducted the meeting on November 27. The address of the evening was delivered by C. H. Bierhaum, on the subject of Bearings.

W. W. BOYD,
Secretary.

CHICAGO SECTION

A joint meeting of the Chicago Section of the A.S.M.E. and A.I.E.E. with the Western Society of Engineers was held in the rooms of the Western Society on Tuesday, November 12. The subject was Industrial Lighting and the War, and Professor C. E. Clewell, of the University of Pennsylvania, delivered an address, illustrated by lantern slides.

A joint meeting of the War Committee of Technical Societies of Chicago was held on November 25 in the rooms of the Western Society of Engineers. Fuel Conservation was the subject of addresses by Preston Millar and Harold A. Almert.

ARTHUR L. RICE,
Secretary.

CONNECTICUT SECTION

The fall meeting of the Connecticut Section was held at New Haven on November 20. The members assembled at the Mason Laboratory at 2:30 p. m. for a trip by automobile to the power plant of the Marlin-Rockwell Corporation and to the new central heating plant of Yale University.

Upon the return of the party a dinner was held at the Mason Laboratory, at 6 p. m., followed by a meeting at Lampson Lyceum, Yale University. The address of the evening was given by Mr. W. H. Blood, of the American International Shipbuilding Corporation, on the Building of Hog Island Shipyard, illustrated by slides and motion pictures.

The Winchester Engineering Club and the Yale University Student Branch of the A.S.M.E. participated in the evening session.

E. H. LOCKWOOD,
Secretary.

NEW YORK SECTION

Albert C. Ritchie, counsel for the War Industries Board and Attorney General of Maryland, spoke at a joint meeting of the New York Section and other technical bodies, held in the Engineering Societies Building, 29 West 39th Street, on November 20. He told of America's part in supplying steel for war needs of this country and the Allies, and predicted an unprecedented demand from Europe for reconstruction purposes.

J. Leonard Replogle, Director of Steel Supply of the War Industries Board, had been announced as the principal speaker of the evening, but J. E. Johnson, Jr., who presided, said that Mr. Replogle had been detained in Washington and delegated Mr. Ritchie to discuss the steel situation.

The speaker, after reviewing at length the achievements of the steel industry in the war, said that the War Industries Board would retain control hereafter over a given industry only when all interests asked for such supervision.

Captain P. E. Dulieux of the French High Commission said that immediate French requirements in the steel line called for 8,000,000 tons. He predicted that, with Alsace-Lorraine back in possession of France, his country might "at a not very distant date be your competitor."

Julius Kahn of Youngstown, Ohio, made an address on the larger uses of reinforced concrete in building operations of the immediate future.

H. D. EGBERT,
Secretary

PHILADELPHIA SECTION

A meeting of the Philadelphia Section was held at the rooms of the Engineers' Club on November 26. J. F. Johnson of the Westinghouse Electric & Manufacturing Co. delivered an address on Large Steam Turbine Design.

J. P. MUDD,
Secretary.

PROVIDENCE ENGINEERING SOCIETY

On November 5, at the Society's rooms, a joint meeting was held, Mr. C. J. Carter of Boston giving an informal talk on Gas Engines for Sea Sleds before the Machine Shop Section. The Power Section was entertained by Talks on Coal—its Production, Distribution and Storage.

The speakers of the evening were Mr. L. D. Moore, Superintendent of Castner, Curran & Bullitt, Inc.; Professor W. H. Kenerson, Director of Conservation for the Rhode Island Fuel Administration, and Mr. A. N. Sheldon, of F. P. Sheldon & Sons, Mill Engineers.

Mr. A. Douglas Wardrop, Managing Editor of Aerial Age, delivered the address on November 8, at Memorial Hall, the subject being My Flight Over the Hindenburg Line, and Latest Developments in Aerial Warfare.

Mr. Edson F. Gallaudet, of the Gallaudet Aircraft Corporation, delivered an address before the Designing and Drafting Section on November 12, the subject being The Application of Some Principles of Airplane Design.

On November 19, Major F. B. Gilbreth, Mem.Am.Soc.M.E., delivered an interesting lecture on the mechanical action of the new designs of Lewis and Browning machine guns, illustrating his lecture with moving pictures of the parts in action.

The Chemical Section heard an interesting address on Some Problems of Gas Warfare by Prof. E. B. Spear, of Massachusetts Institute of Technology.

WILLIAM A. KENNEDY,
Secretary.

NECROLOGY

WALTER ANTOSCH

Walter Antosch was born in New York City on March 17, 1896. He attended the city schools and later Stevens Institute of Technology, from which he was graduated in 1917 with the degree of M.E. For about six months after his graduation he was connected with the Standard Aircraft Corporation, Elizabeth, N. J., serving first in the drafting room, then in the engineering department and finally as assitant superintendent in the production department, where he had charge of routing material through the shops. He resigned his position at the end of that time and enlisted in the United States Naval Reserve Force and was assigned to the Naval Engineering School, where in a very short time he won the rating of machinist. He was then assigned to the U. S. S. *Westbridge*, which was torpedoed on August 15, when he was instantly killed. He was buried on August 28 in the Kerfautras Military Cemetery, Brest, France.

WALTER ANTOSCH

Mr. Antosch also served in the recent Mexican border trouble and was at that time connected with the First Field Hospital of the New York National Guard. He became a junior member of the Society in 1918.

SERGEANT ARTHUR HENRY BERGES

Arthur H. Berges was born on July 28, 1886, in Burlington, Iowa, and was educated in the schools of that city, later attending Purdue University, from which he was graduated in 1910 with the degree M.E. His first employment was with the Chicago & Northwestern Railway Co., Chicago, Ill., as special apprentice. In the early part of 1911 he became connected with the International Harvester Co., and had charge of the production in the tractor works, Chicago. His next position was with the H. W. Schott Co., engineers in Chicago, where his duties gave him charge of construction on the power house of a hydroelectric proposition at Ballville, Ohio. For a short period in 1913 he worked in the mechanical department of Sargent & Lundy, an engineering firm in Chicago, leaving to become draftsman in the shop-engineering department of the Chicago and Western Indiana Railroad Co. At the outbreak of the war he was employed as mechanical draftsman in the Rock Island Arsenal, Ill. He resigned from this position to enlist in the 23rd U. S. Engineers. He was killed in action in France on September 13, 1918.

Sergeant Berges became a junior member of the Society in 1914.

GEORGE GOODWIN CALDWELL

George G. Caldwell was born on June 22, 1857, in Peoria, Ill. He was educated in the public schools of Michigan and at Olivet College, Olivet, Mich. He served an apprenticeship as machinist with the Benjamin & Fischer Co., Chicago, Ill., from 1878 to 1880 and then worked for the next five years in various shops in Massachusetts and Rhode Island, gaining general experience on the construction of steam engines and boilers. About 1890 he became engineer for the Calumet Electric Street Railway Co., Chicago, and installed its plant. Subsequently he went into business for himself as construction engineer. From 1907 to 1909 he was connected with the Wheeler Condenser & Engineering Co., Chicago, erecting and operating machinery. In July, 1910, he entered the employ of H. M. Byllesby & Co. as construction superintendent on installations covering buildings and general power-plant machinery, and remained in that capacity except for a short interim until his death, July 27, 1918. While in this position he had complete charge of the installation of important works for the Oklahoma Gas & Electric Co., Oklahoma City, Okla.; the Northern State Power Co., Minot, N. D.; the Union Light, Heat & Power Co., Fargo, N. D.; the Interstate Light & Power Co., Galena Ill., and the Ottumwa Railway & Light Co., Ottumwa, Ia.

Mr. Caldwell became an associate member of the Society in 1916.

STANLEY SHIELDS COOKE

Stanley S. Cooke was born on August 9, 1893, in Denver, Col., and was educated in the public schools there. He attended the University of Colorado and was graduated in 1915 with the degrees of B.S. and M.E. Upon graduation he was connected for short periods with the following firms: the American District Steam Co., Tonawanda, N. Y., on steam-heating main installations; the Denver Gas & Electric Light Co., Denver, Col., in the transformer department, repairing irons and fans and testing transformers; the Union Pacific Railroad Co., as special apprentice in the motive-power and construction department. He worked for about a year for the Union Metallic Cartridge Co., Bridgeport, Conn., and then took a position with the Lake Torpedo Boat Co., in the same city, on the construction of submarines.

Three weeks after our declaration of war he enlisted in the Navy Coast Guard Service and was sent to Fort Trumbull, New London, Conn., for training and afterwards assigned to the cutter *Tampa*, which left in October to engage in patrol and ascort duty in European waters. In June of this year Mr. Cooke was made first gunner and in August appointed coxswain, and the following month received orders directing his transfer to the Naval Academy to attend the Officers' Training School. On the night of September 26, however, while the *Tampa* was in the British Channel doing escort duty with the fleet, a violent concussion was felt but the cause was not then ascertained. Upon reaching port it was discovered that the *Tampa* was missing. Destroyers immediately set out to hunt for the vessel but apart from a little wreckage, some life preservers marked *Tampa* and two bodies in uniform, nothing else was discovered. The *Tampa* during her year's service abroad had made eighteen trips between Gibraltar and English ports and may be said to have rendered a real service to the Allied cause.

ARTHUR H. BERGES

LIEUTENANT PAUL HENRY CORDES

Lieut. Paul H. Cordes, who was killed in action on the western front in France on September 12, 1918, was born in Altona-Hanover, Germany, on February 17, 1887. He came to this country when he was about eleven years old and was educated in the public schools, later attending evening school, where he took the technical course.

In 1906 he became associated with the Henry R. Worthington Co., Harrison, N. J., works of the Worthington Pump & Machinery Corporation, where he was assistant to the superintendent of the erecting department. His duties there gave him charge of the erecting and testing work on steam and centrifugal pumps, surface condensers, etc. He also assisted in the supervision of the outside construction work. In 1913 he was transferred to the Chicago office as engineering salesman, assisting and having charge of the testing work on large triple-expansion pumping engines, centrifugal pumps and condensers, as well as making experimental and research tests of such machinery, which position he was holding at the time of his enlistment, May 1917. He held the rank of First Lieutenant in Company C, 30th Engineers, Gas and Flame Division.

Lieutenant Cordes became an associate member of the Society in 1916.

SAMUEL AMBROSE FRESHNEY

Samuel A. Freshney was born in January, 1867, in London, England. He was brought to this country when but a child and the family settled in Ohio. His first work was in connection with the electrical business when he was employed by the Brush Electric Co., Cleveland, Ohio. He spent his apprenticeship in the shops of this company and was then promoted to the engineering department. After seven years' service he left to become manager of the Electric Light & Power Co., Muskegon, Ill., where he remained until 1900. For the next two years he was branch manager of the Wayne Electric Works at Cincinnati, Ohio, and Grand Rapids, Mich. In 1902 he was made general manager of the Muskegon Traction & Lighting Co., operating street railway, electric and gas properties, and continued in that capacity until 1905, when he was offered and accepted the position of secretary and general manager of the Grand Rapids Board of Public Works, where he had charge of the water works, electric-light systems, public improvements, streets, sewers, flood protection, etc. In 1912 he resigned from the Board of Public Works to become general manager of the Consumers Power Co., Grand Rapids, Mich., which position he held up to the time of his death, September 16, 1918.

Paul H. Cordes

Mr. Freshney became a member of the Society in 1913.

MAJOR WILLIAM R. KING

Major William R. King, Ordnance, U. S. Army, died at the Post Hospital, Army Proving Ground, Aberdeen, Md., July 18, 1918. A military funeral was held at the Post on the morning of July 20 with the full honors due to his rank and service amid the surroundings which so fully typified his brief but most useful military service.

Prior to the entrance of the United States into the European War, Major King had been an active advocate of preparedness and published an article, A National Factor of Safety, in the *Engineering Record* of January 20, 1915, one of the first comments on the indispensable function of the engineer in modern war and the duty of technical schools to teach military engineering.

Major King was graduated from Stevens Institute of Technology with the class of 1886 and was chairman of the special committee which organized the battalion of 400 Stevens alumni and students in the Preparedness Parade, May 13, 1916. Later he was chairman of the Stevens Alumni Military Committee, placing 250 mechanical engineers in the reserve and civilian service. He, himself, applied for a commission on March 22, 1917.

On October 6, 1917, he was selected for the exceptional duty of Chief of Design and Construction of the new Army Proving Ground at Aberdeen, with its great variety of structures—railroads, highways, docks, power plant, machine shops, gun emplacements, ammunition storehouses and dwellings. He had supervised the erection of a part of the permanent structures and completed much of the temporary work at this proving ground when, on July 17, he was informed of prospective transfer to command at another proving ground and of recommendation for his promotion to the rank of Lieutenant Colonel. Early in the evening of the same day Major King was shot in his room by a man who had apparently no motive except a fancied grievance. The wound proved fatal in twenty-four hours.

William R. King

The following is a record of his principal engineering responsibilities: His first important position was that of assistant superintendent with R. Hoe & Co., New York City, 1886 to 1890; from 1890 to 1894 he was manager and engineer of the Empire State Phosphate Mining Co., an interest of Cooper Hewitt & Co. in Florida; he was next consulting engineer of companies developing respectively an air brake and the King Wyatt resistance type of electric furnace, 1894 to 1897; from 1897 to 1901 he was superintendent and manager of construction of the Oxnard Construction Co., erecting the beet-sugar factories at Oxnard, Cal., at Ames, Neb., and at Rocky Ford, Cal. Thereafter, from 1901 to the time of the war his work was in the field of hydraulic engineering; in particular, the electric plant of the Stanislaus River in California, the Klickitat River development in Washington and the irrigation and electrification projects of the Northern Pacific Railroad Co.

Major King became a member of the Society in 1914.

FRANK E. GETTS

Frank E. Getts was born in Fort Wayne, Ind., in June, 1870, and was educated in the public schools there. From 1887 to 1892 he served his apprenticeship as machinist in the Wabash Railway Shops, Fort Wayne, and for the next three years was connected with the Fort Wayne Electrical Works, first as electrical apprentice and later as construction foreman. His next position was with the Siemens & Halske Electric Co., where he had charge of building and installing electrical generators. He was also with the Northwestern Elevated Railway Co. for a short while. When he became associated with the Chicago Edison Co. in 1903 he was given charge of the installation of all steam turbines at the Fisk Street Power Station. The success of this work was due in great measure to Mr. Getts' personal efforts and his engineering ability. From 1910 to 1913 he had direct charge of all steam work for the General Electric Co. in the Middle West. In October 1913 he resigned from that company to become general manager of the Chicago office of the Alberger Condenser & Engineering Co., and in April 1915 he became general manager of the Electrical Engineers Equipment Co., Chicago, which position he held at the time of his death, May 7, 1918.

Mr. Getts was a member of the American Institute of Electrical Engineers, the Electric Club and the Press Club, Chicago. He became a member of our Society in 1913.

HARRY SHELDON LEONARD

Harry S. Leonard was born on October 21, 1865, in Washington, D. C. He was educated in the public schools of that city and later attended Yale University, from which he received in 1886 the degree of Ph. B. He was connected for about eight years with the New Haven Wire Manufacturing Co. as manager and then spent about a year with the Trenton Iron Co., Trenton, N. J., as sales manager. For the next three years he conducted his own business in Boston as a manufacturers' agent. In 1899 he became manager of the Boston office of the Westinghouse Electric & Manufacturing Co., leaving that firm to become associated with the Winchester Repeating Arms Co., New Haven, Conn., where he remained till about a year ago, when ill health compelled him to resign from the vice-presidency of the company with which he had been connected for eighteen years.

Mr. Leonard became a member of the Society in 1916. He died in New York City on July 26, 1918.

ALBERT THEODORE LEONHARD

Albert T. Leonhard, secretary of the Paterson Parchment Paper Co., Passaic, N. J., died on September 29, 1918, a victim of Spanish influenza.

Mr. Leonhard was born on March 4, 1887, in Haledon, N. J. He attended high school in Passaic and later Stevens Preparatory School from which he went to Stevens Institute of Technology, receiving his M.E. degree in 1908. He became associated in the same year with the Paterson Parchment Paper Co., where he designed and supervised the construction of paper-making and other machinery, improved old and devised new processes for the manufacture of paper; he also designed and supervised the construction of new mill buildings and had general charge of the mechanical department. At the time of his death he held the position of secretary of the firm.

Mr. Leonhard became an associate member of our Society in 1916.

DALE McCARTY

Dale McCarty was born in Gosport, Ind., on January 19, 1892, was educated in the public schools there and later attended Purdue University, from which he received the degree of M. E. in 1911 Upon graduation he worked for a short period with the Western Electric Co., Chicago. In September, 1911, he became connected with the Santa Fe Railroad Co., Chicago, where his duties consisted of steel detailing, layouts, freight and steel passenger-car designs, inspection of material and sketching of foreign-design cars. In the early part of 1914 he resigned from this position to become draftsman with the Enterprise Railway Equipment Co. His work there in the drafting room called for steel hopper, ore, steel and composite ballast, and drop-bottom gondola car designs, stress diagrams and estimates of weight having to be prepared for all cars designed. As mechanical representative of the company he had charge of the general inspection and oversight of deliveries of malleable and steel castings. He was also responsible for the inspection and approval of sample cars in conjunction with the representatives of railroads.

Mr. McCarty had expected to enter the Central Officers' Training Camp in January. He was stricken with Spanish influenza while on a business trip and died in Indianapolis, Ind., on October 18. He became a junior member of the Society in 1916.

WILLIAM EARLE MOSHER

William E. Mosher, who died of pneumonia in Washington, D. C., on October 12, was assistant superintendent engineer of the Army Transport Service, and had been recommended for a commission as Major in the Quartermaster Corps. He was born in 1888 and attended the schools of Mechanicville, N. Y. In 1909 he received the degree of Ph. B. from Syracuse University and in 1911 the degree of M. E. He then attended the Graduate School of the University of Illinois and obtained his M. S. in 1913, having specialized in refrigeration and thermodynamics. From September 1913 to June 1916 Mr. Mosher was assistant refrigeration technologist, U. S. Department of Agriculture, and had charge of the portable precooling plant. His next position was with the Fruit Dispatch Co., New York, as consulting engineer. In January 1918 he obtained leave of absence that he might offer his services to the Government.

Mr. Mosher was a member of the honorary societies of Phi Beta Kappa, Sigma Xi and Tau Beta Pi. He was also a member of the American Society of Refrigerating Engineers. He became a junior member of our Society in 1912.

CAPTAIN WALTER MARANTETTE WILHELM

Capt. Walter M. Wilhelm was born in Defiance, Ohio, on November 13, 1884. He was graduated from the United States Military Academy at West Point, N. Y., in June 1906, and from the School of Ordnance Engineering, Sandy Hook Proving Ground, in July 1909. In August of that year he became assistant and general superintendent at the Watervliet Arsenal, Watervliet, N. Y., the commanding officer being Col. W. W. Gibson. He was in charge of the operation of construction of field and coast guns, specializing in the subject of relining the latter type. He was also responsible for the installation of the Taylor System of manufacture at the Watervliet Arsenal. In 1913 he was transferred to Frankford Arsenal, Bridesburg, Philadelphia, where he was assistant to the officer in charge of the optical department dealing with the manufacture and design of sea-coast instruments. Later he became assistant to the officer in charge and then himself officer in charge of the artillery department at Frankford, where his duties gave him charge of the manufacture and design of shrapnel, shell, time and detonating fuses, hand grenades, rifle grenades, etc., used in the Army and Navy. In November 1915 he resigned from the Army to become vice-president and general manager of the Eddystone Ammunition Corporation, Eddystone, Pa., where he had full charge of the manufacture of 2,500,000 complete rounds of Russian shrapnel. He was holding this position at the time of his death, October 3, 1918.

Captain Wilhelm became a member of the Society in 1916.

ROLL OF HONOR

DIED IN THE SERVICE

Stanley S. Cooke, Coxswain, U. S. S. Tampa, U. S. Navy.

Paul H. Cordes, First Lieutenant, Company C, 30th Engineers, Gas and Flame Division, A. E. F., France.

The following list of those in the Service is made up of the names of members of the Society sent in during the month of November.

Alden, H. W., Lieutenant Colonel, Ordnance Department, U. S. Army; stationed at Washington, D. C.

Anderson, H. W., Private, Chemical Warfare Service, U. S. Army.

Babcock, F. R., Captain, Ordnance Department, U. S. Army.

Bayer, L. C., Coast Artillery Corps, U. S. Army.

Barbieri, Cesare, Lieutenant, Royal Engineers, 2d Regiment, Italian Army, with the Italian High Commission, Washington, D. C.

Beehler, W. P., Commander, U. S. Navy; stationed at U. S. Naval Experimental Station, New London, Conn.

Beekman, Henry M., Second Lieutenant, Ordnance Department, U. S. Army; stationed at Sandy Hook Proving Ground, Fort Hancock, N. J.

Beerbaum, Arthur J., Machinist's Mate, Second Class, U. S. Navy; Steam Engineering, Co. 5, Reg. 17, Great Lakes, Ill.

Bixby, William H., Brigadier General, U. S. Army (Retired); on War Service in U. S.

Bleckley, Logan, Private, 7th Service Co., Signal Corps, U. S. Army; assigned to Ellington Field, Houston, Tex.

Boehnlein, C., Chief Quartermaster, Aviation Co. 31, Naval Aviation Detachment, Massachusetts Institute of Technology, Cambridge, Mass.

Bowen, William S., Second Lieutenant, Signal Corps, U. S. Army; stationed at School of Meteorology, College Station, Tex.

Boyles, Ralph R., Private, 1st Co., 161st Depot Brigade, Camp Grant, Ill.

Bradley, E. P., Captain, Engineering Section, Construction Division, Quartermaster Corps, U. S. Army.

Brizzolara, Robert T., Second Lieutenant, Aviation Section (Aeronautics), U. S. Army; stationed at Park Field, Millington, Tenn.

Brooks, Frederick A., First Lieutenant, Air Service, Aircraft Production, American Expeditionary Forces, France.

Brown, Arthur L., Captain, Engineering Division, Ordnance Department, U. S. Army.

Brown, Owsley, Major, 172d Infantry, American Expeditionary Forces, France.

Bruback, T. M., Second Lieutenant, Research Division, Engineers' Corps, U. S. Army; stationed at Ellington Field, Tex.

Buckingham, J. E. E., First Lieutenant, Co. D, 87th Engineers, U. S. Army; assigned to Fort Benjamin Harrison, Ind.

Burke, Walter S., Lieutenant-Commander, U. S. Navy (Retired); stationed at U. S. Navy Yard, Boston, Mass.

Bursley, Joseph A., Major, Ordnance Department, U. S. Army.

Campbell, E. Gordon, Captain, Engineers' Corps, U. S. Army.

Carter, H. D., Captain, Ordnance Department, U. S. Army.

Carver, E. M., Captain, Engineering Division, Ordnance Department, U. S. Army.

Childs, J. N., Lieutenant, U. S. Naval Reserve Force; stationed as Senior Engineer Officer, U. S. S. *Camden*.

Clancy, W. L., Ensign, U. S. Naval Reserve Force, Line of the Navy, Temporary Staff Duty, Aviation Division, Bureau of Construction and Repair, Washington, D. C.
Conner, B. F., Chief Machinist's Mate, U. S. Navy; stationed at the New York Navy Yard.
Cowles, Clifford A., Jr., Private, Second Class, 5th Service Com. Detachment, Signal Corps, U. S. Army; stationed at Gerstner Field, Lake Charles, La.
Cowperthwait, Allan, Major, Inspection Division, Ordnance Department, U. S. Army.
Cox, James W., First Lieutenant, Quartermaster Corps, U. S. Army.
Crook, W. Ralph, First Lieutenant, Construction Division, Quartermaster Corps, U. S. Army; stationed at Camp Holabird, Md.
Curtis, Allen, Captain, Spruce Production, Air Service, U. S. Army; stationed at Vancouver Barracks, Washington.
De Lany, E. H., Commander, U. S. Navy.
Devine, Charles P., First Lieutenant, Air Service, U. S. Army.
Dismukes, A. R., Co. B, Motor Transport Corps, Unit No. 305, U. S. Army; stationed at Camp Jessup, Atlanta, Ga.
Edwards, G. Middleton, Chief Machinist's Mate, Marine Engineers' Training School, Stevens Institute of Technology, Hoboken, N. J.
Estabrook, Charles B., Captain, Ordnance Department, American Expeditionary Forces, France.
Fischer, Louis A., Major, Gage Section, Engineering Division, Ordnance Department, U. S. Army.
Flewelling, M. F., Jr., U. S. Navy; assigned to U. S. Naval Steam Engineering School, Stevens Institute of Technology.
Fliegner, Carl G., Candidate, 10th Train Battery, Field Artillery Corps, Field Artillery Officers' Training School, Camp Taylor, Ky.
Flynn, John H., Captain, Conservation and Reclamation Division, Quartermaster Corps, U. S. Army; assigned to Camp Johnston, Fla.
Fusselman, P. A., Captain, Co. A, 314th Infantry, American Expeditionary Forces, France.
Gardner, Douglas M., Ensign, U. S. Naval Reserve Force.
Gardner, Thomas, Machinist, Naval Engineering School, Stevens Institute of Technology, Hoboken, N. J.
Garrison, W. L., Second Lieutenant, 301st Mobile Ordinance Repair Shop, American Expeditionary Forces, France.
Grobli, Walter A., Private, First Class, Detached Quartermaster Service, Medical Department, U. S. Army; assigned to General Hospital No. 12, Biltmore, N. C.
Grunert, Arthur E., Captain, Co. D, 4th Engineers, American Expeditionary Forces, France.
Grunwell, Paul C., First Lieutenant, Engineering Division, Ordnance Department, U. S. Army.
Hall, Charles A., Private, Provisional Post Headquarters Co., Training Detachment, Fort Benjamin Harrison, Ind.
Hawkins, Robert D., Lieutenant Colonel, Russian Railway Service Corps, U. S. Army; stationed at Harbin, Manchuria, Asia.
Hazzard, W. S., U. S. Navy; assigned to U. S. Naval Steam Engineering School, Stevens Institute, Hoboken, N. J.
Henszey, Joseph M., Major, Inspection Division, Ordnance Department, U. S. Army.
Hicks, George C., Jr., Major, Ordnance Department, U. S. Army.
Hider, George T., Private, Battery F, 36th Regiment, Coast Artillery Corps, U. S. Army; stationed at Camp Eustis, Va.
Hill, E. Logan, Captain, Engineers' Corps, U. S. Army.
Hill, Herbert M., Private, Science and Research Division, Air Service, Aircraft Production, U. S. Army; stationed at Carnegie Institute of Technology, Pittsburgh, Pa.
Hoopes, Edgar M., Jr., Captain, Utilities Detachment, Quartermaster Corps, U. S. Army; assigned to Camp Meade, Md.
Howard, Cecil D., First Lieutenant, Engineers' Corps, U. S. Army.
Hubbell, Richard L., Second Lieutenant, 109th Infantry, U. S. Army; stationed at Watertown Arsenal, Watertown, Mass.
Hunt, James L., First Lieutenant, Trench Warfare Section, Ordnance Department, U. S. Army.
Imeson, C. V., Captain, Construction Division, Quartermasters Corps, U. S. Army; assigned to Fort Barrancas, Fla.
Jackson, E. E., Private, First Class, Co. M, 22d Regiment Engineers, N. Y. Guard.
Jensen, James A., Second Lieutenant, Research Division, Chemical Warfare Service, U. S. Army; assigned to American University Experiment Station.
Johnson, George A., Major, Construction Division, Quartermaster Corps, U. S. Army.
Jones, Leon B., Candidate, Engineer Officers' Training School, Camp Humphreys, Va.
Kales, W. R., Captain, General Engineering Staff, American Expeditionary Forces, France.
Karcher, Harry E., Private, Co. A, 5th Training Battalion, Signal Corps, U. S. Army; stationed at Fort Leavenworth, Kan.
Kenyon, John T., Major, Ordnance Department, U. S. Army.
King, M. L., Major, Air Service, U. S. Army; stationed at Air Service Flying School, Post Field, Fort Sill, Okla.
King, W. G., Ensign, U. S. Navy.
Knight, Earl L., Sergeant, Co. A, 8th Battalion, Ordnance Department, American Expeditionary Forces, France.
Knox, Carlos C., U. S. S. *Carola IV*, U. S. Navy.
Kouwenhoven, Frank W., Private, Air Service (S.), U. S. Army; assigned to Air Service School for Radio Operators, University of Texas, Austin, Tex.
Lunn, John A., Second Lieutenant, Engineers' Corps, Headquarters Services of Supply, Office of Chief of Chemical Warfare Service, American Expeditionary Forces, France.
Lyons, Karl M., Captain, Oil Branch, Fuel and Forage Division, Quartermaster Corps, U. S. Army.
McLaren, Lewis L., Private, Co. A, Fourth Training Battalion, Signal Corps, U. S. Army; assigned to Fort Leavenworth, Kan.
MacCart, R. D., Ensign, Naval Reserve Flying Corps; assigned to Massachusetts Institute of Technology, Cambridge, Mass.
Malone, J. G., Chief Machinist's Mate, Student, U. S. Naval Steam Engineering School, Pelham Bay, N. Y.
Maloney, Charles A., Ensign, Submarine Unit, New London Base, U. S. Navy; stationed at U. S. Naval Academy, Annapolis, Md.
Meeker, L. A., Captain, Gas Defense Division, Chemical Warfare Service, U. S. Army.
Mills, Harold H., Warrant Machinist, Naval Auxiliary Reserve, U. S. Navy.
Mitchill, George L., Corporal, Co. A, 302d Engineers, Headquarters 77th Division, American Expeditionary Forces, France.
Monahan, W. H., Jr., First Lieutenant, Inspection Division, Ordnance Department, U. S. Army.
Mott, C. S., Major, Quartermaster Corp, U. S. Army; Chief of Production, Detroit District Office.
Moxham, Egbert, Lieutenant Colonel, Ordnance Department, U. S. Army.
Muir, Leonard S., Second Lieutenant, Air Service, Aeronautics, U. S. Army; assigned to Wilbur Wright Field, Dayton, O.
Mullergren, A. L., First Lieutenant, Quartermaster Corps, U. S. Army; assigned to Camp Funston, Kan.
Nash, Douglas E., Ensign, Naval Aviation, U. S. Navy; stationed at Key West, Fla.
Naumburg, Robert E., Second Lieutenant, Air Service, U. S. Army; Engineer Officer First Reserve Wing, stationed at Hazelhurst Field, Mineola, L. I.
Nofsinger, L. E., Private, Air Service, U. S. Army.
Phillips, Leon R., Captain, Construction Division, Quartermaster Corps, U. S. Army.
Philpot, N. E., Chief Machinist's Mate, U. S. Naval Reserve Forces.
Porter, L. L., Ensign, U. S. Naval Reserve Force; stationed at U. S. Naval Academy, Annapolis, Md.
Pratt, Merrill E., Second Lieutenant, Coast Artillery Corps, U. S. Army; assigned to Coast Artillery School, Fort Monroe, Va.
Preston, R. A. D., Lieutenant, Bureau of Construction and Repair (Aviation), U. S. Navy.
Proctor, Redfield, Captain, Engineers' Corps, U. S. Army.
Prussing, R. E., Captain, Quartermaster Corps, U. S. Army.
Purdy, A. R., Private, Air Service, Aircraft Production, U. S. Army; assigned to Second Detachment, N. Y. City.
Roe, J. W., Major, Bureau of Aircraft Production, Air Service, U. S. Army.
Rouse, John E., Candidate, 13th Observation Battery, Field Artillery Corps, Officers' Training School, Camp Taylor, Ky.
Scott, T. Wayne, Sergeant, 111th Infantry, American Expeditionary Forces, France.
Seligman, W., First Lieutenant, Coast Artillery Corps, U. S. Army.
Seth, George L., Lieutenant, Chemical Warfare Service, U. S. Army.
Shepard, F. J., Jr., First Lieutenant, Engineering Division, Ordnance Department, U. S. Army.
Sherry, Samuel E., Jr., Chief Machinist's Mate, Sea-Plane Hangar Co., U. S. Naval Aviation; stationed at U. S. Naval Air Station, Rockaway, L. I.
Sinclair, A. F., Major, Ordnance Department, U. S. Army; stationed at U. S. Ammonium Nitrate Plant, Perryville, Md.
Smith, Cameron C., Major, Production Division, Ordnance Department, U. S. Army.
Smith, Victor J., First Lieutenant, Ordnance Department, U. S. Army; stationed at Frankford Arsenal, Philadelphia, Pa.
Solomon, Gabriel R., Major, Construction Division, Engineers' Corps, U. S. Army.
Spackman, Henry S., Lieutenant-Colonel, Engineers' Corps, American Expeditionary Forces, France.
Stinson, K. W., Second Lieutenant, Air Service (Aeronautics), U. S. Army; assigned to U. S. School of Military Aeronautics, Princeton, N. J.
Swain, Wilbur A., Candidate, 1st Co., Machine Gun Officers' Training School, Camp Hancock, Ga.
Tenkonohy, Franklin V., Captain, 301st Regiment Tank Corps, American Expeditionary Forces, France.
Thompson, John R., Captain, Engineers' Corps, American Expeditionary Forces, France.
Tuvin, J. H., Lieutenant, Utility Co., Construction Division, Army Base Hospital, U. S. Army; assigned to Camp Dix, N. J.
Wadd, Roy J., Second Lieutenant, Chemical Warfare Service, U. S. Army; assigned to Edgewood Arsenal, Edgewood, Md.
Walker, F. W., Jr., First Lieutenant, 4th Anti Aircraft Battalion, Coast Artillery Corps, American Expeditionary Forces, France.

LIBRARY NOTES AND BOOK REVIEWS

REVIEWS of books of special importance to mechanical engineers by members of the Society and those particularly qualified, brief descriptive notes of accessions to the Library of the United Engineering Society, items of interest relating to the Library's activities, etc.

AIRPLANE CHARACTERISTICS. A Systematic Introduction for Flyer and Student and for All Who Are Interested in Aviation. By Frederick Bedell. First edition. Taylor and Co., Ithaca, N. Y., 1918. Cloth, 6 x 9 in., 123 pp., 65 illus. $1.75.

The art of flying, the author states, has progressed so far that the principles of flying can in the main be set forth definitely, and a collection of the essential elements be made that will apply to all airplanes, irrespective of type or structure. He has therefore tried to present a codification of the well-known groundwork, which will give a direct, simple statement of the principles of airplane sustentation and stability and the characteristics of an airplane in flight. The present work only partially covers the subject, but has been issued in its present form to meet the need of the moment.

AMERICAN ASSOCIATION OF ENGINEERS DIRECTORY. Containing Lists of Members Arranged Alphabetically, Geographically and According to Professional Work. Corrected to July 1, 1918. American Association of Engineers, Chicago (copyright, 1918). Cloth, 6 x 9 in., 190 pp., 2 diag., 1 map. $2.

The directory contains an account of the history, aims and organization of the society, with lists of the members arranged alphabetically, geographically, and according to their professional experience.

THE AMERICAN HOSPITAL OF THE TWENTIETH CENTURY. A Treatise on the Development of Medical Institutions, both in Europe and in America, since the beginning of the Present Century. By Edward F. Stevens. Architectural Record Publishing Co., New York, 1918. Cloth, 7 x 10 in., 274 pp., 454 illus. $5.

Mr. Stevens presents plans of and information concerning a number of typical modern institutions, which show various solutions of the problems of housing and treating the sick. He adds also to his illustrations a summary of the results of his own experience in hospital construction and his study of European institutions.

THE ARBITRAL DETERMINATION OF RAILWAY WAGES. By J. Noble Stockett, Jr. Hongton Mifflin Co., New York, 1918. Cloth, 5 x 8 in., 198 pp. $1.50.

This volume of the Hart, Schaffner and Marx Prize Essays is a study of the principles of wage determination and of wage increase advanced by the employees and employers in the course of arbitration proceedings, with a view to ascertaining some fundamental principles which may serve as the basis of a fair and reasonable wage or of a just principle of wage increase. The arbitration proceedings examined number 65 and include those settled under the provisions of the Erdman Act and the Newlands Act, the railway cases under the Industrial Disputes Investigation Act, the Eastern Engineers' Arbitration of 1912 and the Western Engineers and Firemen's Arbitration of 1915.

THE BLUE BOOK OF FACTS OF MARINE ENGINEERING. Including new questions and problems with answers that are required for all grades of Marine and Gas Engine License. Third edition, revised 1918. Ocean Publishing Co., New York (copyright, 1917). Cloth, 4 x 6 in., 116 pp. $2.50.

This quiz compend gives the necessary information for obtaining marine engineers' licenses, in the form of questions and answers. These are classified according to the different grades of licenses.

BOMBS AND HAND GRENADES, BRITISH, FRENCH AND GERMAN. A Handbook Showing Their Construction and Technicalities, Giving Full Instructions as to How to Use and How to Render Useless. By Captain Bertram Smith. E. P. Dutton and Co., New York (copyright, 1918). Cloth, 5 x 8 in., 90 pp., illus., $2.

Descriptions of the types used by the different armies are given, with instructions for their use. Clear outline drawings of each type are included.

DESCRIPTIVE GEOMETRY. By William H. Ames and Carl Wischmeyer. Fifth edition. McGraw-Hill Book Co., Inc., New York. 1918. Cloth, 5 x 8 in., 112 pp., 197 illus. $1.

A condensed course for students in colleges of engineering, in which 72 problems are explained and illustrated, and 400 exercises for solution are presented. The book accords with drafting-office practice by using the third quadrant.

THE FLOTATION PROCESS. By Herbert A. Megraw. Second edition, revised and enlarged. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6 x 9 in., 359 pp., 74 illus., 1 pl., tables. $3.50.

Although litigation over patent rights still continues and there is still no agreement on the theory of the flotation process, the author has thought it advisable to issue a second edition of this work. In it the development of the process, both in theory and practice, is summarized, and an endeavor has been made to present as true a record of present conditions as is possible. Most of the original edition is retained, although some portions that later developments have made valueless are omitted, and considerable new matter has been added.

FUEL ECONOMY IN BOILER ROOMS. A Development of Fuel Economy and CO_2 Recorders Published in the Engineers' Study Course from Power. In two parts. Part I: Fuel Economy and CO_2 Recorders, by A. R. Manjer and Charles H. Bromley. Part II: Fuel Economy in Boiler Rooms, by Charles H. Bromley. Second edition. McGraw-Hill Book Co., Inc. New York, 1918. Cloth, 6 x 8 in., 308 pp., 92 illus., 18 tables. $2.50.

The volume before us contains a revised edition of the book formerly published as Fuel Economy and CO_2 Recorders with the addition of matter on other subjects of interest in connection with efficiency in power-plant operation. The authors have tried to provide a work that will explain in simple language the proper means of attaining fuel economy. For use by firemen and power-plant operating engineers.

GAGES, GAGING AND INSPECTION. A Comprehensive Treatise Covering the Limit System, Measuring Machines, and Measuring Tools and Gages for Originating and Comparing Measurements in the Manufacturing and Inspection Departments, Including Means for Measuring and Inspecting Screw Threads and Gears. By Douglas T. Hamilton. First edition. The Industrial Press, New York, 1918. Cloth, 6 x 9 in., 295 pp., 175 illus. $2.50.

This is the first book, the author says, which deals exclusively with the subject, describes the principles and practical application of the limit system of interchangeable manufacturing and the principal tools and gages in use, comprehensively enough to meet the requirements of today.

GEORGE WESTINGHOUSE. His Life and Achievements. By Francis E. Leupp. Little, Brown and Co., Boston, 1918. Cloth, 6 x 9 in., 304 pp., 5 pl., 6 portraits. $3.

In this account of George Westinghouse, the inventor and the man, the author has gathered his material from such contemporary sources as old newspapers and magazines, corporate reports, court records, local traditions and the personal recollections of the friends and neighbors of Mr. Westinghouse. The trials and failures of his early life, his perseverance in the struggle for the recognition of his air-brake, and his later successes are pictured in detail. The numerous personal anecdotes which are scattered through the book add greatly to the interest of the biography as a human document.

INTERPOLATION TABLES OR MULTIPLICATION TABLES OF DECIMAL FRACTIONS. Giving the Products to the Nearest Unit of All Numbers from 1 to 100 by 0.01 to 0.99 and from 1 to 1000 by 0.001 to 0.999. By Henry B. Hedrick. Carnegie Institution, Washington. 1918. Cloth, 10 x 14 in., 139 pp. $5.

These tables are of especial use in all problems involving the multiplication of decimal fractions of two or three digits where the product is required to no more significant figures than are contained in the smaller factor. Their use may be extended to decimal fractions of three and four digits. As the tables are more accurate than the slide-rule or graphical methods, and more convenient than logarithms, they are of value for many computations where those methods are ordinarily employed.

Life in a Large Manufacturing Plant. By Charles M. Ripley. General Electric Co., Schenectady, N. Y.

A series of pamphlets describing the systematic plans which have been developed for selecting an efficient working force for the General Electric Company and for maintaining a high physical, mental and moral standard.

MacRae's Blue Book. America's Buying Guide. Vol. IX., 1918. MacRae's Blue Book Co., Chicago (copyright, 1918). Cloth, 9 x 12 in., 1345 pp. (advertising pages included). $10.

This directory contains a list of thirty thousand American manufacturers of machinery, tools, and other supplies used by railroads and manufacturers, a list of manufacturers' representatives, a classed directory of makers of different products, an index of trade names, a collection of data useful to purchasing agents, tables of standard prices and a discount computer.

A Manual of Engineering Drawing for Students and Draftsmen. By Thomas E. French. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6 x 9 in., 329 pp., 556 illus. $2.50.

A method of instruction, based upon the conception of drawing as a language, with varied forms of expression, a grammar and style. New chapters on lettering, screw threads, bolts and fastenings, and structural drawing have been added; the chapters on working drawings and architectural drawing have been enlarged, and the text generally revised.

Mechanisms and Mechanical Movements. A Treatise on Different Types of Mechanisms and Various Methods of Transmitting, Controlling and Modifying Motion, to Secure Changes of Velocity, Direction, and Duration or Time of Action. By Franklin D. Jones. First edition. The Industrial Press, New York, 1918. Cloth, 6 x 9 in., 310 pp., 164 illus. $2.50.

The author has classified a variety of mechanical devices representing different types of mechanisms and illustrating important fundamental principles. He has also attempted not only to explain how various mechanical motions may be produced and controlled, but also to show the relation between the theoretical and practical sides of the subject.

Metallurgy of Lead. By H. O. Hofman. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6 x 9 in., 664 pp., 705 illus., 1 folded pl., 153 tables. $6.

This work replaces the author's former treatise on The Metallurgy of Lead and the Desilverization of Base Bullion, but has been so largely rewritten and altered that it has become practically a new book. Only the chapters on reverberatory smelting and German cupellation have been retained in about their original forms. The author has prepared for the new edition by a careful review of the technical literature and by visiting the leading lead plants of the United States and Canada, and has attempted to represent modern practice thoroughly and accurately.

Methods of Measuring Temperature. By Ezer Griffiths. With an Introduction by E. H. Griffiths. Charles Griffin and Co., Ltd., London; J. B. Lippincott Co., Philadelphia, 1918. Cloth, 6 x 9 in., 176 pp., 81 illus., 48 tables. 8s 6d.

This monograph, intended for those concerned with the measurement of temperature in scientific investigations or in the control of industrial operations, is chiefly devoted to the experimental basis of the methods in use, the calibration of the instruments and the precautions necessary in practice. The volume is intended to extend the general treatment given in standard textbooks and to be complete in itself. References to the important literature are given with each chapter.

Mine Tracks. Their Location and Construction. Treating briefly on the Materials Used and the Principles Involved in the Design and Installation, with a Set of Rules for a Standard Practice. By J. McCrystle. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Flexible cloth, 5 x 7 in., 105 pp., 23 illus., tables. $1.50.

The adaptation of mechanical haulage and the successive increases in the weight of mine locomotives and rolling stock are making closer attention to mine tracks imperative, the author says. He has prepared this treatise to furnish a summary of the methods of several companies where systematic attention has been given to the subject, in convenient form for use by those responsible for the planning and maintenance of track work.

Modern Hot Water Heating, Steam and Gas Fitting. By William Donaldson. Frederick J. Drake and Co., Chicago (copyright, 1918). Cloth, 5 x 8 in., 256 pp., 11 illus., 30 tables. $1.50.

An elementary description of apparatus and methods of installing it.

Modern Management Applied to Construction. By Daniel J. Hauer. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6 x 9 in., 194 pp., 19 illus., 1 folded chart. $2.50.

Describes the application of the principles of scientific management to engineering and architectural construction, in the light of the author's experience. An appendix outlines the American and Canadian organizations for war construction.

The Motor Truck as an Aid to Business Profits. By S. V. Norton. A. W. Shaw Co., New York (copyright, 1918). Cloth, 7 x 10 in., 509 pp., 335 illus., 5 folded charts. $7.50.

A collection of plans for using motor trucks in various businesses, showing what has been accomplished in actual practice. The adaptation of the motor truck to a business, its effective and economical utilization, its maintenance and its part in developing the business are discussed in detail.

My Reminiscences. By Raphael Pumpelly. Henry Holt and Co., New York, 1918. Cloth, 844 pp., 57 pl., 24 por., 13 maps, 2 vols. 7.50.

Born in 1837, the author studied geology and mining engineering in Paris and Freiburg, and later led a busy life as a geologist, mining engineer and explorer for over half a century. His professional activities in Asia and America provided an abundance of information on these lands and many adventures and anecdotes, which are presented in an interesting fashion in this autobiography.

Operator's Wireless Telegraph and Telephone Handbook. A Complete Treatise on the Construction and Operation of the Wireless Telegraph and Telephone, Including the Rules of Naval Stations, Codes, Abbreviations, etc. By Victor H. Laughter. Frederick J. Drake and Co., Chicago (copyright, 1918). Cloth, 5 x 8 in., 191 pp., illus., 1 pl. $1.

A student's text, in which he is led from a study of simple elementary systems to the more complicated types of wireless telegraph and telephone instruments. Directions for the construction of instruments are given.

Plane Surveying. A Practical Treatise on the Art of Plane Surveying, Including Chaining, Leveling, Compass and Transit Measurements, Land and Construction Surveying, Topographic Surveying, and Mapping. By J. K. Finch. American Technical Society, Chicago, 1918. Flexible cloth, 5 x 7 in., 243 pp., 154 illus., 11 pl., 10 tables. $1.50.

This manual is especially intended for home study. It is planned to give the practical man a working knowledge of the subject, and to be used by trained surveyors as a convenient review.

A Practical Course in Wooden Boat and Ship Building. The Fundamental Principles and Practical Methods Described in Detail. Especially Written for Carpenters and other Woodworkers who Desire to Engage in Boat or Ship Building, and as a Text-Book for Schools. By Richard Van Gaasbeek. Frederick J. Drake and Co., Chicago (copyright, 1918). Cloth, 5 x 8 in., 204 pp., 119 illus. $1.50.

This text-book is the outgrowth of a course for shipbuilders given at Pratt Institute to assist house carpenters and other woodworkers in transferring from their usual occupations to the shipbuilding industries. The author has attempted to provide a brief, fundamental course in the general principles of construction.

Reinforced Concrete Construction. Part I. With Examples Worked Out in Detail for All Types of Beams, Floors and Columns. By M. T. Cantell, Mem.Am.Soc.M.E. Second edition. Spon & Chamberlain, New York, 1918. Cloth, 5 x 7 in., 160 pp., 75 illus., 1 pl.

The chief object in this work is to endeavor to meet the requirements of students, as well as others who have practical experience but only an elementary knowledge of mathematics and mechanics, for a simple practical treatment of the subject. Part I contains the principles, general information and examples of designing required by the majority of students and practical men. This

edition is revised to comply as far as possible with American and Canadian, as well as British, conditions and practice.

The Second Power Kink Book. A Collection of Short Articles from *Power* in Which Practical Men Describe Simple Expedients They Have Found Effective in Meeting Every-day Emergencies in Power-Plant Work. Compiled by the Editorial Staff of *Power*. McGraw-Hill Book Co., Inc. (sole selling agents), New York, 1918. One-half cloth, 6 x 9 in., 161 pp., 137 illus. $1.

The first Power Kink Book, published in 1917, has led to requests for a further collection of these notes on emergency power-plant practice, in response to which this volume is issued. The book, like its predecessor, is intended to suggest solutions for unusual problems and methods of meeting difficult situations.

Sheet Metal Workers' Manual. A Complete, Practical Instruction Book on the Sheet-Metal Industry, Machinery and Tools, and Related Subjects, Including the Oxy-Acetylene Welding and Cutting Process. By L. Broemel. With a Special Course in Elementary and Advanced Sheet Metal Work and Pattern Drafting for Technical and Trade School Instructors and Students; Also for Reference and Study by Sheet Metal Workers and Apprentices, by J. S. Daugherty. Frederick J. Drake and Co., Chicago (copyright, 1918). Flexible cloth, 5 x 7 in., 552 pp., 394 illus., 32 tables. $2.

The authors have tried to produce a comprehensive text-book on the machinery, tools and methods used in sheet-metal working, suited to the needs of manual training and trade schools. Outline courses in sheet-metal work and hand forging and welding which meet the requirements of emergency war training are included.

The Shipbuilders' Blue Book. This is the first and only practical handbook containing such information as you must have in your daily work. It covers everything on Rivets and Riveting, Spacing of Rivets, Riveting for Water and Oiltight Work, Buttlaps, Buttstraps, Brackets, Frames, Plating, etc., by a Practical Man. By Walter Kay Crawford; edited by E. R. Glass. Ocean Publishing Co., New York, 1918. Cloth, 4 x 6 in., 79 pp. $1.50.

A compact manual of information useful to apprentices and shipfitters; largely in tabular form.

ACCESSIONS TO THE LIBRARY

Aciers fers, fontes. Tome I. By Alexis Jacquet. *Paris, 1918.* Purchase.

Airplane Characteristics. By Frederick Bedell. *Ithaca, 1918.* Gift of author.

Alsace-Lorraine Protests, translated from original French records and published by Mr. D. Fricot. *Angels Camp, Cal. n. d.* Gift of Alfred D. Flinn.

American Institute of Mining Engineers. Transactions. Vol. 57, 58. *New York, 1918.* Purchase.

Association of Ontario Land Surveyors. Annual Report. No. 33, and Proceedings of 26th Annual Meeting. *Toronto, 1918.* Gift of Association.

Bangor Mineral District. (Tasmania. Geological Survey, Bulletin No. 27). *Tasmania, 1918.* Purchase.

Banking Evolution. An address delivered by Chas. H. Sabin, President of the Guaranty Trust Co., before the State Bank Section of the American Bankers' Association, Sept. 25, 1918. Gift of Guaranty Trust Co.

British Columbia, Department of Lands. Report of Water Rights Branch, 1917. *Victoria, 1918.* Gift of British Columbia Water Rights Branch.

Building and Ornamental Stones of Canada. Report. Vol. V. *Ottawa, 1917.* Purchase.

Bureau of Railway Economics. Summary of Railway Returns year ending Dec. 31, 1917. *Washington, 1918.* Gift of Bureau of Railway Economics.

Calcul des systèmes elastiques de la construction. By Ernest Flamard. *Paris, 1918.* Purchase.

California Railroad Commission. Decisions. Vol. XIV, 1917. *Sacramento, 1918.* Purchase.

Catskill Aqueduct Celebration. Historic and Museum Publications, 1917. Gift of Geo. F. Kunz.

Chicago Elevated Railroad Company. Safety Rules. *n. d.* Gift of Company.

Chilean Mining Code, January 1, 1889. By Charles E. M. Michels. *Santiago de Chile, 1914.* Gift of author.

The Co-Insurance Clause. An address delivered before the 129th meeting of the Insurance Society of New York on March 7, 1916. *New York, 1918.* Gift of Insurance Society of New York.

Combination, Not Competition of Railroads. By Blewett Lee. (Reprinted from Michigan Law Review, May, 1918.) Gift.

Diplomatic and Consular Service of the United States. Corrected to Aug. 31, 1918. *Washington, 1918.* Gift.

Duluth-Superior Harbor. Statistical Report of Marine Commerce of Duluth, Minn., and Superior, Wis. *1917.* Gift of Alfred D. Flinn.

L'Elecrochimie et l'Electrométallurgie. By Albert Levasseur. *Paris, 1917.* Purchase.

The Electrician. Annual tables of electricity undertakings of the United Kingdom, the Colonies and Foreign Countries. *London, 1918.* Purchase.

Electrical Blue Book. The Buyers' Encyclopedia of Electrical Material. Ed. 8th, 1918. *Chicago, 1918.* Gift of Alfred D. Flinn.

Engineering Association of New South Wales. Minutes of Proceedings, Vol. XXXII. *Sydney, 1918.* Purchase.

Engineering Profession Fifty Years Hence. By J. A. L. Waddell. (Reprinted from *Scientific Monthly*, Vol. VI, June 1918; Vol. VII, July-Aug. 1918.) *Lancaster, 1918.* Gift of author.

Fares and Freight Rates. What of the Aftermath of Government control of railroads? By H. W. Seaman. (Bulletin No. 46, City National Bank, *Clinton, Iowa*). *1918.* Gift of City National Bank.

Food Supply and the War, as shown by the Report of the New York State Food Supply Commission. *Albany, 1918.* Gift of New York State Food Commission.

Formations Géologiques Aurifères de l'Afrique du Sud. By René de Bonand. *Paris, 1917.* Purchase.

From the Falls to the Factory: a treatise on electric power transmission. British Aluminum Company. *London, n. d.*

Fuel Saving in Power Plants. (Bulletin No. 1, Advisory Engineering Committee to the Massachusetts Fuel Administrator). *Boston, 1918.*

Gravity and Temperature Tables for Mineral Oils from Determinations of the Bureau of Standards and Other Tables for General Testing and Refinery Practice. Compiled and edited by E. N. Hurlburt. *Rochester, 1918.* Gift of Taylor Instrument Companies.

Great Britain. Department of Scientific and Industrial Research. First Report of the Mine Rescue Apparatus Research Committee. *London, 1918.*

—— Report of the Committee of the Privy Council. 1917-18. *London, 1918.* Gift of Department of Scientific and Industrial Research.

Hartford Public Library. Annual Report of the Directors. 18th, 1918. *Hartford, 1918.* Gift of Public Library.

International Military Digest. Annual, 1917. *New York, 1918.* Purchase.

An Investigation into the Therapeutic Value of Compressed Yeast. By P. B. Hawk. (Reprinted from the *Journal of the American Medical Association.*) *New York, 1917.* Gift of The Fleischmann Company.

Jane's Fighting Ships, 1917. An encyclopedia of the navies of the world. *London, 1917.* Purchase.

Kingdom of Belgium. Ministry of Justice and Ministry of Foreign Affairs, War of 1914-1916. Reply to the German white book of the 10th May, 1915, Die völkerrechtswidrige Führung des belgischen volksriegs. *London, 1918.* Gift of Service Bureau of the Committee on Public Affairs.

Proctor Knott's Speech on Duluth, issued by the Public Affairs Committee of the Commercial Club of Duluth. Gift of Alfred D. Flinn.

La Distillation Fractionnée et la Rectification. By Charles Mariller. *Paris, 1917.* Purchase.

Laying the Rails for Future Business, with a synopsis of the Law for the Federal Control of Railroads. *New York, 1918.* Gift of Guaranty Trust Company.

Lessons in Community and National Life. Series A, for the upper classes of the high school. *Washington, 1918.* Gift of U. S. Bureau of Education.

Merchants' Association of New York. I. Opposing Government Ownership and Operation of Public Utilities; II. Advocating Exclusive Regulation of All Railroads by the Federal Government. Nov. 1916. Gift of Merchants' Association of New York.

Metropolitan Water Board. 12th Annual report on the results of the chemical and bacteriological examination of the London waters for the twelve months ended 31st March, 1918. By A. C. Houston. *London, 1918.* Purchase.

Minerals and Metals for War Purposes. Hearings before the Committee on Mines and Mining, United States Senate, 65th Congress, Second Session. *Washington, 1918.* Gift.

Mining Operations in the Province of Quebec, 1917. *Quebec, 1918.* Purchase.

National Advisory Committee for Aeronautics. Annual Report. 3d, 1917. *Washington, 1918.* Gift of A.S.M.E.

New Orleans, La. Sewerage and Water Board. Report, 36th semi-annual. *New Orleans, 1917.* Gift of Sewerage and Water Board.

New York State. Chamber of Commerce. Annual Report of the Corporation. 60th, 1917-18. *New York, 1918.* Gift of Chamber of Commerce.

New York State. Public Service Commission, Second District. Annual Report. 1917—II. *Albany, 1918.* Gift of New York State Public Service Commission.

New York Times Index. April-June 1918. Volume VII. *New York, 1918.* Purchase.

Ogden City, Utah. Monthly Financial Statement, May 1918, also containing summary of proceedings of the Board of Commissioners for the month of May 1918. Gift of City Recorder.

Oil, Paint and Drug Reporter. Green book for buyers. Fall edition, 1918. *New York, 1918.* Gift of Oil, Paint & Drug Reporter.

Pennsylvania. Department of Agriculture. Feeding Stuffs Report, 1917. (General bulletin No. 312). *Harrisburg, 1918.* Purchase.

Pocket List of Railroad Officials, No. 95, 1918. *New York, 1918.* Purchase.

Portland Cement Association. Magazine List, August, 1918. *Chicago, 1918.* Gift of Association.

Public Utilities Reports—Annotated, 1918 (—) B. C. *Rochester, 1918.* Purchase.

Recent Revolution in Organ Building. By G. L. Miller. Ed. 2. *New York, 1913* Gift of Samuel Wein.

Reconnoissance Soil Survey of North Eastern Wisconsin, with maps. (Bulletin No. XLVII to L, Soil Series 12-15.) *Madison, 1916.* Purchase.

TRADE CATALOGUES

Bigelow Company. New Haven, Conn.
Catalogue describing the Bigelow Hornsby water-tube boiler. 1917.

Burt Manufacturing Company. Akron, Ohio.
General catalogue on oil filters, exhaust heads and ventilators. 1917.
Blue print of Burt unit-type filter. 1914.

Defender Automatic Regulator Company. St. Louis, Mo.
Catalog No. 10. n. d.

E. I. du Pont de Nemours & Company. Wilmington, Del.
Blasters' Handbook. 1918.

General Electric Company. Schenectady, N. Y.
Bulletin No. 40017. Small Direct Current Generators, Type ML. August 1918.
——— No. 47702. Rheostat and Compensator Operating Mechanisms. August 1918.

General Electric Company, Ivanhoe Regent Works. Cleveland, Ohio.
Catalog No. 276. Ivanhoe metal reflectors and fittings for industrial illumination. 1918.

Harrison Safety Boiler Works. Philadelphia, Pa.
Catalog No. 550. Cochrane Steam and Oil Separators.
——— No. 710. Cochrane Heaters for Steam Power Plants.
Engineering Leaflet No. 18. Testing V-Notch Meters.
Cochrane Exhaust Steam Heating Encyclopedia. 1914.

Jeffrey Mfg. Co. Columbus Ohio.
Catalog No. 175. Jeffrey Standard Belt Conveyers.

Larner-Johnson Valve and Engineering Company. Philadelphia, Pa.
Bulletin No. 1. Johnson hydraulic valve. July, 1918.

New England Tank and Tower Company. Everett, Mass.
Wood tanks. (Catalogue F.)

Reynolds Electric Company. Chicago, Ill.
Bulletin No. 22. Reco color hoods. June 15, 1915.
——— No. 27. Reco flashers. July 1, 1915.
——— No. 33. Reco flashers. Dec. 1, 1915.
——— No. 202. Type "A" alternating-current motors.

Ross Heater and Manufacturing Company. Buffalo, N. Y.
Catalogue B. Ross crosshead-guided expansion joint.

Richardson Scale Company. Passaic, N. J.
Descriptive booklet describing Richardson automatic scales for pulverized coal.

Smith Serrell Company, Inc. New York City.
Bulletin No. 26. Francke flexible couplings. 1918.

Stephens-Adamson Mfg. Co. Aurora, Ill.
The Labor Saver. October 1918.

Tide Water Oil Company. New York, N. Y.
Veedol, lubrication of internal combustion engines. Ed. 4, 1918.

United Filters Corporation. Brooklyn, N. Y.
Sweetland's patent metallic filter cloth.

Wheeler Condenser and Engineering Company. Carteret, N. J.
Bulletin 112-A. Condensers, pumps, cooling towers, etc. 1918.

Worthington Pump and Machinery Corporation. New York, N. Y.
Vertical triplex power pumps, single and double acting. (D-702) May, 1918.

Yarnall Waring Company. Philadelphia, Pa.
Engineering devices for the power plant. Descriptive booklet.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by December 15 in order to appear in the January issue.

CHANGES OF POSITION

Otto Da Costa-Schmidt, formerly affiliated with the Treadwell Engineering Company, Easton, Pa., has entered the employ of the Ohio Bronze Powder Company, Cleveland, Ohio.

Sidney G. Walker, until recently associated with the Manufacturers' Mutual Fire Insurance Company, Providence, R. I., has assumed the position of vice-president of the New York Reciprocal Underwriters, with headquarters at New York.

O. G. Jenner has resigned his position of superintendent with the Wilson and Bennett Manufacturing Company, Chicago, Ill., to assume a similar position with the Equipment Corporation of America, of the same city.

Adolph Starr has entered the employ of the Locomotive Superheater Company, New York, in the capacity of erecting engineer. Mr. Starr was, until recently, chief gage inspector, Winchester Repeating Arms Company, New Haven, Conn.

Harry E. Henrickson, formerly connected with the S. S. White Dental Manufacturing Company, has become associated with the Remington Arms and Ammunition Company, Bridgeport Works, as a process engineer.

William V. Lowe, formerly associated with the engineering department of John Bath Company, Fitchburg, Mass., has assumed the duties of foreman of the training school of the Putnam Machine Company, Fitchburg, Mass., which is one of the branches of the Manning, Maxwell and Moore Company. The training school, or vestibule school, has been established throughout the country to provide workmen for the shop to take the places of those who have gone to the front.

J. D. Goulette has accepted the position of construction engineer with the Gulf Production Company, Eastland, Tex. He was, until recently, affiliated with the Gulf Refining Company, Shreveport, La., in the capacity of construction engineer and plant superintendent.

George S. Blankenhorn, resigned from the American International Shipbuilding Corporation, on August 1, as engineer of steam machinery, and since then has been connected with the Wilson-Snyder Pumping Machinery Company, as engineer in their Philadelphia, Pa., district.

Louis J. Pelissier, formerly equipment engineer of the Norwich, Conn., Division of the Marlin Rockwell Corporation, is now mechanical superintendent of the Tacony, Philadelphia Division of the same company.

J. H. Romann, formerly connected with the Chicago, Ill., office of Joseph T. Ryerson and Son, is now in charge of the export division of the company in New York, which has recently been opened.

John G. Shirley, assistant works manager of the Gilbert and Barker Manufacturing Company, Springfield, Mass., has accepted an appointment as production manager of the S. K. F. Ball Bearing Company, Hartford, Conn.

Percy A. McKittrick, for 20 years with the Saco-Lowell Shops and the Lowell Machine Shop, has severed his connection with that company and is now assistant treasurer of the Parks-Cramer Company, of Fitchburg, Mass. The Parks-Cramer Company is a recent consolidation of two firms well known in mill circles, the G. M. Parks Company, of Fitchburg, Mass., and Stuart W. Cramer, of Charlotte, N. C.

Frederick A. Alden, formerly connected with Fay, Spofford and Thorndike, Boston, Mass., as mechanical engineer, has assumed the duties of division engineer, Sea Service Bureau, United States Shipping Board, Boston, Mass.

Lewis H. Miller has become affiliated with the Babcock and Wilcox Company, Barberton, O., in the capacity of designing engineer of the plant engineering department. He was formerly associated with the Tennessee Coal, Iron and Railroad Company, Birmingham, Ala., as mechanical engineer.

George H. John, Jr., until recently planning engineer with the Stokes and Smith Company, Philadelphia, Pa., has assumed the duties of instructor in mechanical engineering, Columbia University, New York.

John B. Purves, formerly associated with the Combined Locks Paper Company, Combined Locks, Wis., has resigned his position and has assumed the duties of mill manager with the Interlake Pulp and Paper Company, Appleton, Wis.

Stephen H. Painter has become special representative of the Ingersoll-Rand Company, in Chile and in Bolivia. He was formerly associated with the company in New York, as manager of the calyx drill department.

Philip M. Hathaway has resigned his position with the International Register Company, Chicago, Ill., to become chief engineer of the National Lead Company, Crooke Works, Brooklyn, N. Y.

JOHN W. MI[illegible], plant engineer at Bayles Shipyard, Inc., Port Jefferson, N. Y., is now employed in the ship construction department of the American International Shipbuilding Corporation, Hog Island, Pa.

STEPHEN THOMAS, formerly combustion engineer for the Goodyear Tire and Rubber Company at Akron, Ohio, has accepted a similar position with the E. I. du Pont de Nemours Company, Wilmington, Del.

ANNOUNCEMENTS

F. H. ROSENCRANTS has entered the engineering department of the Electric Bond and Share Company, New York.

A. H. PUGH has accepted the position of head of the loading and explosive section, Ordnance Department, Cincinnati, Ohio.

RUPERT K. STOCKWELL, formerly western manager, Robins Conveying Belt Company, Salt Lake City, Utah, has assumed the duties of general sales manager of the same company, with headquarters at New York.

CHARLES E. WADDELL has assumed the office of Chief of Conservation for North Carolina, under the United States Fuel Administration.

LIEUTENANT WILLIAM P. HAYES, United States Naval Reserve Force, is now in command of one of the United States vessels on the Asiatic Station.

LIEUTENANT FRANK P. BOYD, U. S. N. R., since the war chief engineer of the U. S. S. *Jupiter*, a 20,000-ton electrically propelled ship, has been stationed as engineer and repair officer, Submarine Base, New London, Conn., and has been promoted to Lieutenant Commander, U. S. N. R.

FRED V. HADLEY, consulting engineer for industrial furnaces, Boston, Mass., has closed his office to become associated with Tate-Jones and Company, of Pittsburgh, with headquarters at 50 Church St., New York.

FRANK MOSSBERG has assumed the duties of vice-president and general manager of the Hooker-Mossberg Corporation, which has recently been organized in the state of Massachusetts to take over a large contract for the manufacture of airplane parts for the Government. The factory is located at Attleboro, Mass.

FRANK C. GIGNOUX has assumed the duties of production expert, Bureau of Aircraft Production, U. S. A., Berkeley, Cal.

CHARLES W. WILLETTE has accepted a position with the California Barrel Company, of San Francisco and Portland, and is engaged in drawing plans for an immense plant comprising a sawmill and barrel factory combined which, when completed, will cover about 60 acres. Mr. Willette's headquarters are in Portland, Ore.

H. HOWARD HELLER has become associated with the Ford Instrument Company, New York, N. Y.

JULIUS ALSBERG has entered the Division of Fats and Oils of the U. S. Food Administration with headquarters at Washington, D. C.

JAMES C. HOBART, with the American Red Cross Ambulance Service in Italy, has been decorated by the Government for meritorious conduct in a recent offensive.

APPOINTMENTS

F. E. MATTHEWS, specializing in mechanical refrigeration, and engaged for several months past in research work of a physico-chemical nature in connection with the commercial development of a new system of refrigeration based on chemical reaction, has accepted an appointment for the duration of the war with the United States Department of Agriculture, Bureau of Markets, with headquarters in New York. He will have to do with the study of cold storage methods and costs to the end of assisting the industry in the establishment of an equitable and uniform basis for determining operating costs of chilling, freezing and carrying various cold storage products under refrigeration.

G. P. SONN has recently been appointed plant engineer of the National Conduit and Cable Company, Hastings, N. Y.

HENRY S. MORSE has been appointed chief engineer of the St. Joseph Lead Company at Herculaneum, Mo.

J. J. SWAN has been appointed Lieutenant-Colonel, U. S. Army, and assigned to the Personnel Branch of the Operations Division, General Staff, Washington, D. C.

A. F. BARNES, Dean of Engineering, New Mexico College of Agriculture and Mechanic Arts, has been appointed by the United States Fuel Administration, administrative engineer for New Mexico.

H. O. C. ISENBERG, formerly assistant factory manager of the Wright-Martin Aircraft Corporation, has been appointed factory manager of the corporation's New Brunswick, N. J., plant.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

POSITIONS AVAILABLE

Stamps should be inclosed for transmittal of applications to advertisers; non-members must accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

DIRECTOR OF WELFARE WORK and general plant coöperation with heads of departments and employees. Location, Middle West. L-0282.

DRAFTSMEN on industrial plant and power-station work. Traveling expenses and salary depending on man: $45 per week. Location, Wilmington, Delaware. L-0662.

MECHANICAL AND SAFETY ENGINEER having two or more years practical shop experience. Must be tactful and able to confer with high executives and Government officials. Excellent opportunity to make wide acquaintance in engineering profession. Salary $1800 to $2500. L-0767.

DRAFTSMAN, with experience in design of medium weight machinery. Responsible man. Steam-engine experience valuable. Pay according to experience and ability. Location, Buffalo. L-0768.

WORKS ENGINEER, technically trained, high class executive, to take charge of architectural and construction departments, complete power equipment, stock storage and transfer problems. Preference given to man with general manufacturing experience in addition to specializing on above problems. L-0770.

HIGH-GRADE MAN to take charge of heat-treating department, Indianapolis firm. Technically-trained man of energy, ambition and executive ability, to take hold of department and make it highly productive both in quality and quantity of work done. Some experience in carbonizing and cyaniding of steels. Fundamental grounding in heat treatment of steels and ability to trace causes through results. Should be capable executive and have genius sufficient to improve plant and equipment conditions. Position one of large opportunities. Salary $250 per month. Location, Indianapolis. L-0771.

INSTRUCTOR in practical mathematics for two or three evenings a week. Practical man preferred. L-0772.

DIRECTOR, toolmakers-apprentice school. Location, Utica, N. Y. L-0773.

MAN with aptitude for writing and engineering training and experience, training preferably in mechanical engineering to include familiarity with power-plant practice. Commercial and selling experience, and originality and interest in technical and commercial developments of advantage. Work can be so arranged that it can be done either largely at desk or combined with certain amount of traveling and interviewing of engineers and business men. Physical inability, interfering with getting about freely, would not necessarily disqualify. State training and experience and if possible send samples of own authorship. L-0774.

ASSISTANT GENERAL MANAGER, manufacturing of automobile parts in the way of transmissions, steering gears, differentials, clutches and controls for automobile trucks and tractors. At present employing 1600 men in factory with floor capacity of about 300,000 square ft. High-grade man with considerable experience in manufacturing and executive work. L-0782.

ENGINEERS AND DESIGNERS, high-grade men for permanent work. L-0784.

DESIGN AND LAYOUT MAN, not over 35, married man preferred. General knowledge of electrical construction with sufficient practical or technical training to lay out well-balanced design, together with knowledge of quantity production. Required for mechanical design of lighting, starting and ignition equipment for internal-combustion engines. Salary up to $175 per month. Location, Indiana. L-0786.

DRAFTSMAN for plant in Jones Point, N. Y. Salary $25 per week with transportation and meals. Prefer experience in chemical or sugar line. Application in hand writing. L-0787.

SALES ENGINEER, to assist with portion of engineering correspondence and problems, requiring man of technical education or training, with view to recommending and selecting proper sizes of ball bearings for various applications to fill requirements of clients. Location, Connecticut. L-0788.

MECHANICAL DRAFTSMEN, two or three for Government work. L-0797.

ENGINEER, competent to take charge of gas-engine plant, consisting of three Smith producers, two Allis-Chalmers engines, direct connected to two Bullock generators of 200-kw. each. Location, New York. L-0803.

TECHNICAL MEN in connection with experimental-engineering department, to determine by time-study method output of each operation; also study of speeds and feeds, to enable rate department to set piece rates. L-0805.

SAFETY ENGINEER, preferably with technical training, to carry on inspection service, education and committee work connected with large corporation. Location, Utica, N. Y. L-0806.

DRAFTSMAN on design-conveying machinery. Location, New York. Salary depends on man. L-0810.

MECHANICAL ENGINEER for engineering division in St. Louis Ordnance District, with considerable experience in machine design and shop practice. Capable of writing comprehensive letters concerning manufacture of ordnance material. Salary about $3000 a year. Desirable that man be familiar with manufacturing conditions of section. L-0813.

ASSISTANT INSTRUCTOR in Lowell Textile School, mechanical drawing, engineering department. Prefer man with some teaching experience. Could use one good draftsman. Salary $25 per week. L-0814.

SALES ENGINEER, age 28 to 35; keen, aggressive, tactful, pleasing personality. One who will not lose sight of engineering principles in desire for trade, willing to build from foundation up. Engineer with selling experience or salesman with engineering knowledge. Knowledge of ball-bearing field desirable. Location, Chicago. Salary $3000 to $4000. L-0815.

CHIEF INSPECTOR, age 35 to 40, electrical and mechanical; resourceful and systematic with organizing and executive ability. Thorough training with considerable practical experience in manufacturing small electrical devices. Knowledge insulating materials and very intricate processes incident to building wire-wound insulated apparatus. Good practical knowledge machine-shop practice, operation, testing and inspection. Location, Indiana. State salary. L-0816.

SHOP MANAGER AND DESIGNER on machine tools, especially engine lathes. State experience in detail during past ten years, capacity for producing results and salary expected. Location, Cincinnati. L-0818.

TWO INSTRUCTORS in mechanical drawing and descriptive geometry. Location, Hoboken, N. J. L-0819.

CHIEF ENGINEER, technical graduate, preferably mechanical; over 30 years of age, with good experience. Wanted for concern making pipe and pipe-bending machinery. Location, Harrisburg, Pa. L-0820.

FIELD INSTRUCTOR in mechanical-engineering extension division University of Wisconsin. Location probably at Milwaukee. L-0821.

YOUNG ENGINEER, at least five years' experience since graduation with operation and maintenance of mechanical equipment; an assistant master mechanic. Salary $250 per month. L-0822.

DESIGNER AND DRAFTSMAN, 30 to 40 years old. Single men preferred. Position permanent; designing ability in gas-engine electrical work of from ½ to 5 kw. capacity. Production is small gas engine electric-direct electric-connected unit. Salary $2400 and up. Headquarters at Dayton, Ohio. L-0823.

GAS ENGINEER, one capable of testing meters, calculating flow of gas, handling all mechanical details connected with gathering and distributing natural gas. Location, Oklahoma. L-0825.

ASSISTANT for material inspection needed. Man versed in actual inspection and tests of boiler tubes, boiler plate, ship plate and structural steel for ships. Essential that applicant be conscientious and absolutely trustworthy. Accuracy in mathematics required and references desired. Salary $175 per month, together with arrangement regarding traveling expenses. L-0827.

MECHANICAL DRAFTSMAN for essential work around furnaces and mines. State age, experience, reference and salary expected. L-0828.

ASSISTANT PURCHASING AGENT familiar with electrical equipment. Must be familiar with purchasing methods to obtain definite promises of delivery, and able to follow these up and see that promises are kept. Salary about $200 per month to start. Location, Middle West. L-0829.

FIRST-CLASS PRODUCTION MANAGER. Capable of supervising clerical record, thoroughly familiar with brass and aluminum foundry methods and machine shop and assembling practice. Department is in charge of handling all orders through factory and keeping machinery and other facilities properly employed, maintaining shipping dates and stock requirements with greatest possible degree of accuracy. Salary $4000 to $4500 per year. Location, Detroit. L-0831.

FACTORY-PLANT ENGINEERS. General manager and assistant general manager for manufacturing paper. Age 25 to 40. Salary $300 per month. Headquarters, Paterson, N. J. L-0832.

ASSISTANT TO ENGINEER in charge of construction work; Government proposition in Southern Jersey. Man familiar with C. E. fundamentals and office work in connection with varied construction. Salary $275. L-0833.

CHEMIST AND METALLURGIST. Foundry work. Salary depends on applicant's ability. Location Middle West. L-0836.

MAINTENANCE ENGINEER. Familiar with machine-shop practice, maintenance, and mechanical engineering. Shop work. Salary depends on applicant's ability. Location Middle West. L-0837.

MECHANICAL ENGINEER, experienced in design of high-grade steam engines and boilers, especially of the marine type. Thoroughly experienced man with good record required, and one able to handle draftsmen. Give age and experience in detail and salary desired. Location, Pa. L-0838.

CHIEF ENGINEER, familiar with design of structural and plate work, hoisting and conveying machinery of the heaviest type. Must have executive ability of highest order. Give age and experience in detail and salary desired. Location, Pa. L-0839.

WORKS MANAGER for plant located in middle west, manufacturing high-grade medium and heavy metal-working machinery. Must be at present similarly employed and have had extensive machine-tool experience, be a good organizer with years of experience in handling men; must be from plant with not less than 600 men under his direction. L-0845.

MEN AVAILABLE

Only members of the Society are listed in the published notices of this section. Copy for notices should be on hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

MECHANICAL ENGINEER. Age 31, 11 years' experience on maintenance and installation of mechanical and electrical equipment of machine shops, automobile factories, and cotton mills. At present plant engineer of large machine shop employing 3000. Salary $3000. L-283.

SUPERINTENDENT OR CHIEF ENGINEER of power plants or superintendent of plant and factory construction. Specially trained in handling large work in best engineering practice. Ten years' practical experience since graduation from technical school. American, age 33 years, ready to go anywhere. Now employed but can obtain release when necessary. Design, construction, operation, and maintenance of plants a specialty. L-284.

MECHANICAL ENGINEER, technical graduate and associate member, desires position as manager where executive ability is necessary with an extensive knowledge of modern scientific and production management. Held positions of superintendent and factory manager and with consulting industrial engineers. Will consider proposition only where high-grade man is required. Available about January 1. L-285.

MANAGER OR SUPERINTENDENT. Technical graduate; 20 years' experience in the manufacture of machine tools, gasoline engines, and electrical machinery in positions from machinist to manager. Also experienced in equipment of buildings and in use of modern methods in plant management and production engineering. At present superintendent. L-286.

PRODUCTION, EFFICIENCY ENGINEER, 15 years' technical and practical experience covering all branches of manufacturing. Have pleasing personality; six years as executive. At present with one of the largest automotive companies. Desire association with financial business man or promotor requiring man of ability to organize new business or give new life to an old one. Any correspondence must be confidential and proposition high-grade and essential. L-287.

MECHANICAL ENGINEER, age 30, eight years' broad experience. Last four years as chief draftsman on design, construction and maintenance in power plant of large public service company, and still so employed. Desires engineering position with large manufacturing or public utility company. L-288.

PRODUCTION OR PRODUCTION EQUIPMENT ENGINEER, or other responsible position, designing or manufacturing end or both. Salary about $4000. Would like to correspond with party needing self-starting man. Practical mechanic and designer. Experience covers originating, designing, building and operating numerous special and standard automatic and semi-automatic machines for producing wide variety of articles from wire, sheet metals, paper, wood, etc., for assembling, labor saving, processing, conveying, cost reducing, etc.; punches and dies, jigs, fixtures and tools and general engineering routine, cost accounting, bookkeeping, time study and production. Twenty-eight years old, married, with family. Will go anywhere. L-289.

EXECUTIVE, graduate naval architect and mechanical engineer. Member, ten years' broad practical experience in shipbuilding, steel-plate construction, oil engines and special machinery, filling positions of chief draftsman, engineer, works manager and general manager. Available January 1. Salary $5000; familiar with modern accounting, cost keeping, production and manufacturing methods and all phases of plant equipment, maintenance and operation. L-290.

MANAGER, GENERAL SUPERINTENDENT OR SUPERINTENDENT. Industrial engineer, member, American, age 42. Twenty-one years' broad experience covering design, manufacture, construction and operation, appraisal and investigation, cost analysis, purchasing and management, special machinery in manufacturing machine shops, covering engines, boilers, overfeed and underfeed stokers; kilns, dryers and metallurgical furnaces, pumps, condensers, evaporators and distillers; mining, conveying, transmission and process machinery; machine shop, power, water works, cotton-seed oil, cement, hydrated lime and chemical plant design; operation construction and direction during past ten years; at present on large Government plant construction. Seeks responsible permanent connection. Salary minimum $6000 per year to start. L-291.

MECHANICAL ENGINEER with eight years' experience in design and manufacturing. One year experimental and research engineering on rifles and machine guns and small interchangeable parts. Technical graduate. L-292.

SUPERINTENDENT, WORKS MANAGER, PRODUCTION SUPERINTENDENT, shell-forging plants, shipyards, machine or structural shops. Salary $4000 to $5000. Location preferably in the East. L-293.

SALES MANAGER OR SALES ENGINEER. American, 13 years' experience covering designing, construction, manufacturing and selling. Have initiative and ability to get results. At present employed as sales engineer; five years with large manufacturer; desires change about January 1, 1919. L-294.

EXECUTIVE, SALES ENGINEER, highly successful, desires change. Available January 1, 1919. Fifteen years' experience in Eastern territory dealing with executives, managers and consulting engineers almost entirely, and selling with the largest concerns in the country. Graduate mechanical engineer, good correspondent, well connected. Salary and commission preferred. Willing to make a moderate start with the right concern. L-295.

MECHANICAL ENGINEER, associate member, age 36, experienced in design, manufacture, sale and installation of rubber and wire machinery. Can show a successful record for 20 years, last five years as chief engineer of small plant manufacturing above lines. Desires position as chief engineer or chief draftsman of larger plant or as chief engineer of rubber or wire factory. Location East or Middle West. Available on 30 days' notice. Salary $4000. L-296.

WORKS ENGINEER. Graduate mechanical engineer. Thirty-three years old. Three years' shop experience, six years with leading steel-car manufacturing company; three years steel works. Active and energetic. Now employed. Will go anywhere. L-297.

INDUSTRIAL ENGINEER, three and a half years' experience installing scientific management methods. At present connected with prominent engineering concern doing this type of work. Desires position which involves little or no traveling. Age 27, married; available January 1. L-298.

POWER-PLANT ENGINEER, technical graduate, age 32, married; eight years' experience in steam-power plants, recently employed as superintendent of power. At present engaged in war work. Wish permanent position in power-plant operation, design of construction. L-299.

MECHANICAL ENGINEER, American, 23, four years apprentice as machinist in smelter, will graduate from Rensselaer in January. L-300.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER DECEMBER 21

BELOW is a list of candidates who have filed applications since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. The total number of applications listed below is 153.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by December 21, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE MEMBER

Alabama

MACGUIRE, JAMES, Chief Inspector, Power Plant Equipment, Air Nitrates Corporation, Muscle Shoals

MIDDLEMISS, GEORGE H., Superintendent, Maintenance and Repairs, Alabama Power Company, Birmingham

PERRY, HARRY M., Southern District Manager, Ingersoll Rand Co., Birmingham

California

HELLERMAN, GEORGE N., Chief Engineer, San Diego Electric R. R., San Diego

KING, PETER M., Mechanical Engineer, General Petroleum Corporation, Vernon

MARDEL, CHARLES M., Chief Engineer, Oakland Antioch & Eastern R. R., Oakland

WILSON, WILLIAM W., Vice-President, Treasurer and Manager, Wilson & Willard Manufacturing Company, Los Angeles

Colorado

WOOLFENDEN, HENRY L., District Manager, Allis-Chalmers Manufacturing Company, Denver

Connecticut

BREITENSTEIN, ALBERT F., Designing Engineer and Chief Draftsman, The Geometric Tool Company, New Haven

BRISTOW, WILLIAM, Mechanical Engineer, Ordnance Department, U. S. A., Remington Arms, Bridgeport

BURNS, ROBERT H., Engineer, Remington Arms Company, Bridgeport

HALLOCK, HENRY E., Equipment Engineer, Marlin-Rockwell Corporation, New Haven

SMITH, PETER L., Superintendent, Power Department, Winchester Repeating Arms Company, New Haven

VAN SCHAACK, DAVID, Director, Aetna Life Insurance Company, Hartford

WOOD, BURTON S., Teacher of Manual Training, Driggs School, Waterbury

Delaware

SWAYZE, WILLIAM W., Mechanical Engineer, Wilmington

District of Columbia

HORWITZ, SAMUEL S., Captain of Engineers, U. S. A., Washington

Illinois

BUHMEYER, CLAUDE H., Assistant Production Manager, Free Sewing Machine Company, Rockford

CURRIER, CHARLES H., Vice-President, Drying Systems, Inc., Chicago

McBRIDE, HERBERT K., Structural & Mechanical Engineer, Wilson & Company, Chicago

PRITCHARD, RALPH W., Engineer Assistant to Manager, The Pullman Company, Pullman

SHAW, ENOS L., Civil Engineer, Chicago

SHUMATE, FRANK D., Mechanical Sales Engineer, Worthington Pump & Machinery Corporation, Chicago

WILSON, ALEXANDER H., Assistant Chief Draftman, Amalgamated Machinery Corporation, Chicago

Indiana

CRAWFORD, CHARLES S., Assistant General Manager and Chief Engineer, Premier Motor Corporation, Indianapolis

SIMS, ERNEST M., Secretary, Treasurer and Factory Manager, Metal Forming Corporation, Elkhart

Iowa

STODDART, FRANK P., Chief Mechanical Engineer, Murray Iron Works Company, Burlington

Maryland

BATHURST, ARTHUR F., Mechanical Superintendent, Crown Cork & Seal Company, Cartridge Manufacturing Division, Baltimore

HERITAGE, ARTHUR M., Engineer, U. S. Army, Edgewood

Massachusetts

AUDET, HERBERT R., Captain, U. S. Government Arsenal, Springfield Armory, Springfield

BRISTOL, BENNET B., Treasurer, The Foxboro Company, Foxboro

BUDLONG, GUY V., Power Engineer, American Steel & Wire Company, Worcester

HALL, WALTER B., Agent, Thorndike Company, Warren Cotton Mills, West Warren

HOOK, HENRY C., General Foreman, Norton Grinding Co., Worcester

KEOUGH, PETER F., General Mechanical Superintendent, Springdale Finishing Company, Canton

MANN, WILLIAM D., Chief Engineer, American Incandescent Heat Company, Roxton

MITCHELL, JOHN H., Plant Engineer, Hamilton Woolen Company, Southbridge

ROCHE, WESLEY C., 1st Lieutenant, Ordnance Department, Watertown Arsenal Production, Watertown

Michigan

HILL, WILLIAM C., Plants Engineer, Northwestern Leather Company, Sault Ste Marie

TAYLER, THERON C., Assistant Mechanical Engineer, Ford Motor Company, Detroit

TURNBULL, JOHN G., Mechanical and Electrical Engineer, Albert Kahn & Associates, Detroit

New Hampshire

FARMER, NOYES D., Supervisor of Costs, Atlantic Corporation, Portsmouth

HARMON, HARRY T., Master Mechanic, The Atlantic Corporation, Portsmouth

New Jersey

BELLER, IGNATIUS, Designing Engineer, Balbach Smelting & Refining Company, Newark

SPILLMAN, MAX, Works Engineer, Henry R. Worthington, Harrison

WHITNEY, OSCAR C., Engineer, Pintsch Compressing Company, Jersey City

New York

BAILEY, RAYMOND C., Expert Aid, Electrical and Mechanical, Public Works Department, New York Navy, New York

DICKINSON, JOSEPH H., Engineer and Manager, Logging Machinery Department, Lidgerwood Manufacturing Company, New York

HOFFMAN, WILLIAM H., Mechanical Engineer, Ford, Bacon & Davis, New York

LOGAN, WILLIAM, SR., Superintendent, James Stewart & Company, New York

McLEAN, EMBURY, Treasurer and Chief Engineer, The Engineer Company, New York

PFARRE, EDGAR G., Chief Engineer, George Tiemann & Company, New York

SEXTON, FRANK B., Manager of Sales, Van Blerck Motor Company, New York

SPRAGUE, LUCION C., Assistant Secretary and District Manager, Chicago Pneumatic Tool Corporation, New York

STORER, HARRY D., District Manager, New York City, Kerr Turbine Company, Wellsville

WAGNER, JULIUS H., Proprietor, Sheet Metal Contracting Business, Brooklyn

WEARIN, FRANK W., Engineer, Selson Engineering Company, New York

WILSON, JAMES A., Lieutenant, Naval Overseas Transportation Service, U. S. A., New York

Ohio

CAIN, JOHN N., Locomotive Engineer, Ashtabula

FISHBOUGH, HARRY E., Mechanical Engineer, The Hoppers Manufacturing Company, Springfield

MARSH, EDWARD L., Vice-President and Treasurer, The Bay View Foundry Company, Sandusky

SPROULL, JOHN C., Balloon Engineer, The B. F. Goodrich Company, Akron

Pennsylvania

BINZ, GUSTAV A., Sales Manager, Yarnall-Daring Company, Philadelphia

BRAEMER, WM. G. R., Consulting, Air Conditioning and Industrial Engineer, Philadelphia

KING, ALVIN W., Sales Manager, Nelson Valve Company, Philadelphia

RUSHTON, KENNETH, Chief Mechanical Engineer, The Baldwin Locomotive Works, Philadelphia

UZELMEIER, WILLIAM, Assistant Chief of Engineering Department, Harrison Safety Boiler Works, Philadelphia

WAGNER, CLYDE A., Construction Engineer, The Barrett Company, Philadelphia

WEBSTER, HOWARD J., Consulting Engineer, President, Uniflow Boiler Company, Philadelphia

Rhode Island

BIGELOW, FRED C. JR., Mechanical Superintendent, River Spinning Company, Philipsdale

STAHL, NICHOLAS, General Engineer, Narragansett Electric Lighting Company, Providence

Texas

PRATT, CLARENCE E., Consulting Engineer, Seymour

Wisconsin

CAHILL, CHARLES A., Administrative Engineer, Wisconsin Federal Fuel Administration, Milwaukee

Canada

FROST, EDGAR R., Mechanical Superintendent, Metals Chemical, Ltd., Welland, Ontario

McROBERT, WILLIAM M., Manager, Galt Foundry Company, Ltd., Galt, Ontario

ROBERTS, THOMAS L., Consulting Mechanical and Marine Engineer, Winnipeg

Cuba

CAMP, LEE G., Chief Engineer, Cuba Cane Sugar Corporation, Habana

Federated Malay States

SCOTT, JOHN MURRAY, Engineer, Nova Scotia Estate, Perak

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

California

O'NEILL, Paul A., Superintendent, Union Machine Company, San Francisco

Illinois

HOFSTETTER, Robert, Mechanical Engineer, Illinois Tool Works, Chicago

New York

BURNS, Raymond W., Estimator, Watervliet Arsenal, Watervliet

Ohio

KLEMIN, Alexander, 2nd Lieutenant, in charge Aeronautic Research Section, A. E. D. McCook Field, Dayton

RYDER, James C., Aeronautical Mechanical Engineer, Bureau of Aircraft & Production, Dayton

Pennsylvania

REIBER, Harry P., Mechanical Engineer, Oil Well Supply Company, Pittsburgh

Texas

SCHMAUDER, Walter G., Superintendent of Power, Texas Power & Light Company, Dallas

Wisconsin

SHUTE, Robert L., Works Engineer, The Albert Trostel & Sons Company, Milwaukee

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Illinois

DIBBLE, Claude M., Erecting Engineer, Shell Division, Pullman Company, Pullman

WALTERS, Russell J., Tool Designer, Ordnance Department, Rock Island Arsenal, Rock Island

Maryland

KERR, George M., 1st Lieutenant, C. W. S., U. S. Army, Edgewood Arsenal, Edgewood

Massachusetts

HOWARD, Stanley R., 1st Lieutenant, Ordnance Department, U. S. A. Watertown Arsenal, Watertown

Michigan

CHATFIELD, Victor M., Chief Engineer, Bostaph Engineering Corporation, Detroit

New Jersey

BAKER, Edward, Superintendent Webb Wire Works, New Brunswick

GESELL, William H., General Manager, Hamersley Manufacturing Co., Garfield

OLSON, Oscar W., Leading Draftsman, Stationary Drafting Department, Babcock & Wilcox Company, Bayonne

New York

MILLER, Ralph, Erecting and Service Engineer, De La Vergne Machine Company, New York

PAGE, George A., Chief in Charge of Patent Department, also Auxiliary Engineer Mechanical Division, Bausch & Lomb Optical Company, Rochester

TITTERINGTON, Morris M., Chief Engineer, Aircraft Section, Sperry Gyroscope Company, Brooklyn

Ohio

DAY, Alfred C., Captain, Chemical Warfare Service, U. S. A., Chillicothe

McHUGH, Edwin C., Consulting Engineer, Cincinnati

VERKAMP, Walter F., Secretary and Engineer, The Ohio Electrolytic Oxygen Company, Cincinnati

Pennsylvania

CUSHMAN, Paul A., Assistant Professor of Mechanical Engineering, Penn State College, State College

PETTY, John, President and General Manager, Lebanon Boiler Works, Lebanon

Wisconsin

BERKELEY, Lawrence J., Vice-President and Chief Engineer, Hercules Manufacturing Company, Racine

France

GOSS, Leonard K., 1st Lieutenant, Ordnance, U. S. A., American Expeditionary Forces

VAN WYCK, Philip S., 2nd Lieutenant, c/o Co. A, 67th Engineers, American Expeditionary Forces

FOR CONSIDERATION AS JUNIOR

Connecticut

ATHERTON, Russell, Chief Machinist Mate, U. S. Naval Experimental Station, New London

DUPONT, Andrew T., Machinery Scientific Section, Lake Torpedo Boat Co., Bridgeport

RICE, Kenneth A., Ensign, U. S. N. R. F., Naval District Base, New London

Delaware

ANDERSON, Walter C., Engineer, The Continental Fibre Company, Newark

SMITH, Malcolm H., Designer, E. I. DuPont de Nemours & Company, Wilmington

District of Columbia

FARDELMANN, John H. Jr., Mechanical Draftsman, Engineering Bureau, War Department, Washington

MATHER, Thomas H., Ship Draftsman, Bureau of Construction & Repair, Washington

OLIPHANT, Abner C., Assistant Head, Gauge Branch, Inspection Division, Ordnance Department, U. S. A., Washington

STIRLING, Harry H., Lieutenant, U. S. Navy, Bureau of Steam Engineering, Washington

Illinois

CONZELMAN, J. Wilson, Assistant to District Steam Engineer, American Steel & Wire Company, Waukegan

TOBEY, Tom, Assistant Boiler House Foreman, Corn Products Refining Company, Argo

Maryland

PECK, Winfield F., Supervisor of Air Brakes, Baltimore & Ohio R. R., Baltimore

Massachusetts

ARONSON, Mark, Mechanical Section, Boston Navy Yard, Boston

SCHLICHTER, Louis R., Draftsman and Designer, Navy Yard, Boston Hull Division, Boston

WIESNER, Maurice W., Supervising Engineer of Test, Inspection Division, Ordnance Department, Boston

Michigan

PETERSON, Paul J., Assistant Chemist, Henry Ford & Son, Dearborn

New Jersey

ANTHONY, Sidney R., Machinists Mate, U. S. Navy, Hackensack

HOOT, Harold T., Mechanical Engineer, Oxweld Acetylene Company, Newark

New York

BASSETT, Gerald L., Chief Draftsman, Savage Arms Corporation, Utica

BERBERICK, John R., Draftsman, United Gas & Electric Engineering Corporation, New York

BURRILL, Harold G., Chief Engineer, Utica Gas & Electric Company, Utica

LO, Ying Chun, Calculator, American Locomotive Company, Schenectady

MING, Frederick W., Instructor of Mechanical Engineering, Polytechnic Institute of Brooklyn, Brooklyn

POSNACK, Emanuel R., Assistant to Production Engineer, Standard Shipbuilding Corporation, Shooters Island

Ohio

BROWN, Robert H., Engineer in charge of materials testing, Airplane Engineering Department, U. S. A., McCook Field, Dayton

Pennsylvania

LYNCH, Frank M., Hull Engineer, Bethlehem Shipbuilding Corporation, Bethlehem

WEISCOPF, Marcus W., Assistant Aeronautical Mechanical Engineer, Naval Aircraft Factory, Philadelphia

WOLF, Morris, Designer, H. Koppers Company, Pittsburgh

Virginia

RAMSEY, Alexander M., Mechanical Draftsman, Mathieson Alkali Works, Saltville

Wisconsin

NEKRASOFF, Alexis M., Draftsman in Maintenance Department, Allis-Chalmers, Milwaukee

Porto Rico

FIOL, Ignacio, Assistant Engineer, Fortuna Sugar Factory, Fortuna

CHANGE OF GRADING
PROMOTION FROM ASSOCIATE

Connecticut

MERKT, G. A., Chief Engineer, The American Tube & Stamping Company, Bridgeport

PROMOTION FROM ASSOCIATE-MEMBER

Connecticut

CARTER, Oscar S., Mechanical Engineer, Connecticut Light & Power Company, Waterbury

Illinois

DANIELS, George C., Mechanical Engineer, Central Illinois Light Company, Peoria

New York

MILLETT, Kenneth B., Assistant General Engineer, American Thread Company, New York

Pennsylvania

BACHMAN, B. B., The Autocar Company, Ardmore

PROMOTION FROM JUNIOR

California

GARRETT, John A., Mechanical Engineer, Fairbanks Morse & Company (Reinstatement), Los Angeles

Connecticut

ELIN, Michael B., Engineer, Colt's Patent Fire Arms Manufacturing Company, Meriden

District of Columbia

SCHLINK, Frederick J., Associate Physicist, Bureau of Standards, Washington

Illinois

GATELY, William A., 1st Lieutenant, Ordnance Department, U. S. A., Rock Island Arsenal, Rock Island

PARSONS, Harry N., Sales Engineer, U. S. Ball Bearing Manufacturing Company, Chicago

New York

ESTABROOK, Mansfield, Captain, Ordnance Department, U. S. A. Inspector of Ordnance, Remington Arms Union Metallic Cartridge Company, Ilion

JONES, Russell C., Vice-President, The Griscom-Russell Company, New York

KENT, Robert T., Supervising Engineer, Meyer, Morrison & Company, Inc., New York

Ohio

JEHLE, Ferdinand, Service Engineer, The Aluminum Castings Company, Cleveland

Rhode Island

FISHER, Howard C., Manager, Engineering Department, Frank A. Sayles, Pawtucket

Virginia

HENLEY, Earl K., Lieutenant, U. S. N. R. F., U. S. S. Jupiter, Norfolk

SELECTED TITLES OF ENGINEERING ARTICLES

The section Selected Titles of Engineering Articles comprises an index to current articles on mechanical engineering and related subjects.

This work has been made possible by the remarkable collection of current technical periodicals available in the Library of the United Engineering Society, which is one of the greatest and most complete collections in the world. The Library receives, even now, when some of the foreign periodicals have ceased to come to its shelves, close to a thousand different papers, magazines and transactions of societies in the engineering and scientific fields, in not less than ten languages. The Society's engineering staff examines these publications as they are received from day to day and prepares the descriptive items which are ultimately used in the Selected Titles section of THE JOURNAL.

Chief attention is paid to articles directly concerned with the branches of mechanical engineering. When it is thought they will be of interest or value to mechanical engineers, however, other articles are listed, in the realms of physics and chemistry; civil, mining and electrical engineering, technology, etc.; and in subjects in broadly related fields such as training and education, safety engineering, fire protection, employment of labor, welfare work, housing, cost keeping, patent law, public relations, etc. Cross-references are introduced and where the titles themselves are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of page 1096.

PHOTOSTATIC PRINTS

Photostatic copies may be obtained of any of the articles listed in this section.

Price of each print (up to 11 x 14 in. in size), 25 cents, plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Orders should be sent to
HARRISON W. CRAVER, *Director,*
Engineering Societies Library,
29 West Thirty-ninth Street,
New York.

ACCOUNTING

Highways

Classification of Expenditures for Highway Cost Accounting. Good Roads, vol. 16, no. 19, Nov. 9, 1918, pp. 178-180. Outline of system proposed in recent publication of Office of Public Roads and Rural Engineering.

Handling Materials

Coke Loading Tipples in the Municipal Gas Works at Düsseldorf (Die Koksverladebrücke des Stadtischen Gaswerkes Düsseldorf). Journal für Gasbeleuchtung, year 61, no. 10, Mar. 9, 1918, p. 117, 1 fig.

AERONAUTICS

Aerostatics

Military Aerostatics, H. K. Black. Aerial Age, vol. 8, no. 4, Oct. 7, 1918, p. 169, 1 fig. Observation balloon in Navy. (Continuation of serial.)

Altitude Flight

The Flight of an Aeroplane at Different Altitudes, Louis de Bazillac. Translated from original French by B. Bruce-Walker Flight, vol. 10, no. 30, July 25, 1918, pp. 836-837, 4 figs. The logarithmic diagram-formulae for resistance and total lift for unit speed. (Concluded.)

Atlantic Flight

Atlantic Flight, M. A. S. Riach. Times Eng. Supp., no. 528, Oct. 1918, p. 216. Analysis of possibility of constructing an aeroplane capable of making journey in single flight.

British Aeroplanes

The Sopwith Camel Flight, vol. 10, no. 37, Sept. 12, 1918, pp. 1019-1022, 14 figs. Description of machine (F. 1. B. 6290) built by Sopwith Aviation Co. Translated from German paper. Also in Aviation, vol. 5, no. 6, Oct 15, 1918, pp. 361-362, 6 figs.)

Engineers, Aeronautical

The Education of Aeronautical Engineers Aeronautics, vol 15, no. 250, July 31, 1918, p. 96 Account of work being done in France

Engines

The 180-hp. Mercedes Aircraft Engine. Automotive Ind., vol. 39, no. 11, Sept 12, 1918, pp. 153-156, 9 figs. Fuel test results and table of data of development of 160-hp model, having same cylinder dimensions, compression increased and details redesigned.

The Design of Airplane Engines (VI), John Wallace. Aeronautics, vol. 15, nos. 253, 254, 256, 257, 258, 259, Aug. 21, 28, Sept. 11, 18, 25, Oct. 2, 1918, pp. 163-164, 4 figs. 200-202, 1 fig., 236-238, 5 figs., 267-269, 7 figs., 295-297, 9 figs., 317-320, 15 figs. Aug. 21: Torque reaction; side-thrust upon cylinder walls; Désaxé cylinder; Aug. 28; weight/power ratio; weight/cylinder capacity ratio; rotary motor; power/cylinder capacity ratio; weight/power ratio; mean effective pressure; Sept. 11: Volumetric efficiency; pumping losses; gas velocity; speed of revolution, effects of increased inertia forces; piston speed; speed of propeller shaft; cylinder dimensions; stroke to bore ratio; Sept. 18: Cylinder design; objections to cast cylinders; example of side-valve cylinder; overhead valve cylinder construction; valve ports; valve guides; Sept. 25: Construction and mounting of cylinders; water jackets; colonnette bolts; strength of cylinders; 160-hp. Benz cylinder; Mono Gnome cylinder; detachable cylinder heads; Oct. 2: Poppet valves; materials for valves; proportions of valves; operation of slide valves; valve springs; operation of overhead valves; Beardmore gear; camshafts; openings and timing valves.

The 300-hp. Maybach Engine. Flight, vol. 10, nos. 35, 37, 38, Aug. 29, Sept. 12, Sept. 19, 1918, pp. 962-965, 10 figs., 1031-1035, 12 figs., 1059-1063, 12 figs. Aug. 29: General features; details of cylinder, pistons, gudgeon pins, and floating small-end bushes. Issued by Tech. Dept., Aircraft Production, Ministry of Munitions; Sept. 12, Propeller hub; lubrication, crankcase ventilation; constructional details of oil pumps; Sept. 19, carburetors; resistance test; atomization test; petrol pump; delivery tests; starting gear. Issued by Tech. Dept. Aircraft Production Ministry of Munitions. Also published in Aeronautics, vol. 15, no. 255, Sept. 4, 1918, pp. 216-223, 15 figs.; Engineer, vol. 126, no. 3271, Sept. 6, 1918, pp. 194-196; 9 figs.; Aviation, vol. 5, nos. 6 and 7, Oct. 15, 1918, pp. 357-360, 10 figs., and Nov. 1, 1918, pp. 429-433, 13 figs.

French Aeroplanes

The French A. R. Biplane with 190-hp. Renault Motor. Flight, vol. 10, no. 38, Sept. 19, 1918, pp. 1053-1057, 12 figs. Description of machine (translated from German paper). Also in Aviation, vol. 5, no. 7, Nov. 1, 1918, pp. 423-424, 7 figs.

German Aeroplanes

German Airplane Albatros D. V. (Avion allemand Albatros D. V.) L'Aérophile, year 26, nos. 13, 14, July 1-15, 1918, p. 203, 3 figs. Scheme and dimensions.

New German Airplanes (Nouveaux avions allemands). L'Aérophile, year 26, nos. 13, 14, July 1-15, 1918, pp. 199-201, 6 figs. General characteristics of Pfalz D III, Fokker D VII, Halberstadt CII, and Riesenflugzeuge.

Report on the A. E. G. Armored Aeroplane, J. G. Weir. Aeronautics, vol. 15, no. 255, Sept. 4, 1918, pp. 212-214, 12 figs. Issued by Tech. Department, Aircraft Production, Ministry of Munitions. Also in Engineer, vol. 126, no. 3271, Sept. 6, 1918, pp. 206-207, 11 figs.; Aviation, vol. 5, no. 6, Oct. 15, 1918, pp. 367-368, 3 figs.; Flight, vol. 10, no. 35, Aug. 29, 1918, pp. 969-972, 15 figs.

Report on the Hannoveraner Biplane. Aeronautics, vol. 15, no. 256, Sept. 11, 1918, pp. 239-245, 21 figs. Particulars of enemy machine. By Technical Department, Aircraft Production, Ministry of Munitions.

Report on Two-Seater Rumpler Biplane, C 117 Aeronautics, vol. 15, no. 256, Sept. 11, 1918, pp. 245-249, 22 figs. Details of enemy machine using 260-hp. Mercedes engine. By Technical Department, Aircraft Production, Ministry of Munitions. Also in Flight, vol. 10, no 37, Sept. 12, 1918, pp. 1025-1030, 25 figs

Some Fokker "Milestones." Flight, vol. 10, no. 35, Aug. 29, 1918, pp. 966-967, 8 figs. Development of Fokker firm since outbreak of war.

The German Airplane, Pfalz D. III. (L'avion allemand Pfalz D. III.) L'Aérophile, year 26, nos. 13, 14, July 1-15, 1918, pp. 193-198, 6 figs. Details of planes, tail, fuselage, motor and armament.

The Pfalz Single Seater Fighter (II). Automotive Ind., vol. 39, nos. 11 and 12, Sept 12 and 19, 1918, pp. 462-463, 3 figs., and 503-505, 6 figs. Mounting of tail plane, tail skid, vertical fin and rudder and construction of these parts. Sept. 19: Seating arrangement—aileron, elevator, rudder controls; landing gear. (From Flight.) Also in Engineer, vol. 126, no. 3274, Sept. 27, 1918, pp. 270-272, 16 figs.

The Zeppelin Giant Airplane. Aviation, vol. 5, no. 6, Oct. 15, 1918, pp. 365-367, 6 figs. Wire-bracing; ailerons; vertical fins and rudders; internal arrangements; armament; undercarriage, controls; weight items. (Concluded.)

Model Aeroplanes

Model Aeroplane Building as a Step to Aeronautical Engineering. Aerial Age, vol. 8, no. 4, Oct. 7, 1918, p. 181, 10 figs. Construction of a 20-ft. glider. (Continuation of serial.)

Model Aeroplanes (XV), F. J. Camm. Aeronautics, vol. 15, no. 253, Aug. 21, 1918, p. 176, 1 fig. Rudiments of aerofoil theories. (To be continued.)

Performance, Aeroplane

Airplane Performance Determined by Engine Performance, G. B. Upton. Jl. Soc. Automotive Engrs., vol. 3, no. 4, Oct. 1918, pp. 275-279, 3 figs. Curves showing altitude against engine speed for various efficiencies and speed ratios, also curves showing engine and propeller power at different altitudes and ceiling height for conventional and theoretical constant power engine.

Propellers

Air Propeller Performance and Design by the Specific Speed Method, M. C. Stuart. Practical Engr., vol. 58, no. 1648, Sept. 26, 1918, pp. 148-150, 3 figs. Rotational speed and diameter of propeller being expressed in terms of power and forward velocity, a direct method of treatment obtained. (To be continued.)

Research

British Advisory Committee Report for 1917-1918. Aviation, vol. 5, no. 6, Oct. 15, 1918, pp. 368-370. Account of experimental work at National Physical Laboratory in aerodynamics and strength of construction.

The National Physical Laboratory Report, 1917-1918. Aeronautics, vol. 15, no. 255, Sept. 4, 1918, pp. 226-227. References to aeronautical work.

Third Annual Report of the National Advisory Committee on Aeronautics. Aerial Age, vol. 8, no. 4, Oct. 7, 1918, pp. 174-175. Board of war inventions in aeronautics; metric system for drawings and calculations; technical reports; general problems and activities. (Continuation of serial.) Also in Aeronautics, vol. 15, no. 256, Sept. 11, 1918, pp. 250-253.

Stresses in Structure

Stresses in Airplane Ribs, Irving H. Cowdrey. Aviation, vol. 5, no. 7, Nov. 1, 1918, pp. 425-428, 5 figs. Transverse testing under non-uniformly distributed load with special application to airplane wing ribs. Before Am. Soc. for Testing Materials.

The Stresses in a Fuselage in Torsion, H. A. Webb. Aeronautics, vol. 15, no. 250, July 31, 1918, pp. 105-106, 4 figs. Method of approximation based on assumption that wires are initially unstretched and torsion is carried entirely by wires, the struts and longerons merely holding them in position.

Trajectory, Aeroplane

Trajectory of Airplane Equipped with a Fuselage. (Trajectoire de l'aéroplane à nacelle), L. Farand, L'Aérophile, year 26, nos. 13 and 14, July 1-15, 1918, pp. 204-208, 12 figs. Mathematical computation of hodograph based on assumption that the angle of the planes with the trajectory remains constant and that the force of propulsion remains always horizontal.

See also Engineering Materials (Aeroplane Fabrics); Internal-Combustion Engineering; Standards and Standardization (Aircraft Materials); Wood (Aeroplane Woods).

AIR MACHINERY

Air Supply to Boiler Room

The Air Supply to Boiler Rooms, Richard W.

Allen. Engineer, vol. 126, no. 3271, Sept. 6, 1918, pp. 198-199, 10 figs. Considering chiefly air supply to closed stokeholds. Paper before Instn. of Naval Architects, March 1918.

Blowers

Blower for Water-Tube Boiler Plant at Bristol Electricity Works. Engineering, vol. 106, no. 2744, Aug. 2, 1918, pp. 126. 13 figs. Drawings of boiler and blower arrangements.

Compressed Air

The Use of Compressed Air (l'emploi de l'air comprimé), M. C. F. Bernard. L'Echo des Mines, no. 2594, Oct. 6, 1918, pp. 507-508. Disposal of water of condensation collecting in compression chamber and conduits.

Wind Power

Some Long Island Windmills, Edward P. Buffet. Am. Mach., vol. 49, no. 16, Oct. 17, 1918, pp. 725-729, 10 figs. Illustrated description of century-old grist mills.

Utilization of Wind Power (Om Udnyttelse af Vindkraften), H. C. Vogt. Ingeniren, year 27, no. 79, Oct. 2, 1918, pp. 521-522.

See also Internal-Combustion Engineering (Gas Engines).

BRICK, CLAY AND STONE

Abrasion Test

Abrasion Test for Mineral Aggregates, H. H. Scofield. Good Roads, vol. 16, no. 12, Sept. 21, 1918, pp. 108 and 110. Suggested modification of Deval test for stone, gravel and similar materials.

See also Testing and Measurements (Sand); Power Generation and Selection (Quarry).

BRIDGES

Concrete Bridges

Recommended practice for Concrete Bridge Construction. Cement & Eng. News, vol. 30, no. 8, Aug. 1918, pp. 30-34, 2 figs. General specifications, prepared by engineers of Portland Cement Assn., based on recommendations of committee on Bridges of Am. Concrete Inst. and on parts of Bul. no. 10 of Illinois State Highway Department, a Manual for County Superintendents of Highways, Resident Engineers, and Inspectors.

Recommended Practice in Design and Construction of Permanent Highway Bridges of Concrete and Steel, John W. Towle. Mun. & County Eng., vol. 55, no. 4, Oct. 1918, pp. 144-145. Features of three types: flat slabs or box culverts, girder with two or more heavy stringers; circular or elliptical bridge.

Standard Practice in Concrete Bridge Construction, H. Colin Campbell. Eng. & Cement World, vol. 13, no. 6, Sept. 15, 1918, pp. 11-16, 6 figs. Considerations to determine suitable type of highway bridge for a given location.

Old Bridges

Investigating Old Bridges for Heavier Loading, C. F. Loweth. Ry. Age, vol. 65, no. 17, Oct. 25, 1918, pp. 741-745, 1 fig. Abstract of paper at convention of Am. Ry. Bridge & Building Assn., Chicago, Oct. 1918.

Quebec Bridge

The New Quebec Bridge. Engineering, vol. 106, no. 2750, Sept. 13, 1918, pp. 237-281, 23 figs. A fully illustrated account.

Trunnion Bearing

Repairing a Bascule Bridge Trunnion Bearing. Ry. Age, vol. 65, no. 18, Nov. 1, 1918, pp. 771-772, 3 figs. To insert a new bushing it was necessary to lift an entire span, weighing about 800 tons.

BUILDING AND CONSTRUCTION

Dams

Dams for $20,000,000 Miami Conservancy. Contracting, vol. 7, no. 9, Nov. 1, 1918, pp. 276-277, 5 figs. Construction of earth embankments containing up to 4,000,000 yd. with excavated material transported on cars, dumped into sumps, and pumped to place.

Foundations

Reconstructing Foundations of Philadelphia City Hall (II). Contracting, vol. 7, no. 9, Nov. 1, 1918, pp. 271-272, 3 figs. Replacement of rubber footings by heavy concrete sectional construction built in sheeted pits 6 ft. long.

Integral Forms

Concrete Construction with Integral Forms. Contracting, vol. 7, no. 9, Nov. 1, 1918, pp. 273-274. Utilization of elements of permanent structure eliminating steel and wood temporary forms.

Masonry Building

Guatemala Earthquakes Destroyed All Masonry Buildings, Edward Stuart. Eng. News-Rec., vol. 81, no. 14, Oct. 3, 1918, pp. 623-626, 8 figs. Wood and concrete frames stood shocks well; wrecked sanitary services to be rebuilt under direction of Red Cross engineers.

Piers

Building B. & O. R. R., Pier No. 9, Baltimore. Contracting, vol. 7, no. 9, Nov. 1, 1918, pp. 274-275, 3 figs. Replacement of 160 x 850 ft. burned pier and freight house.

The Furness-Withy Company Reinforced Concrete Pier at Halifax, N. S., A. F. Dyer. Contract Rec., vol. 32, no. 35, Aug. 28, 1918, pp. 692-695, 5 figs. Work being done in construction of a pier 590 ft. long by 90 ft. wide, carrying a single-story shed 514 ft. by 70 ft.

Shops

New Shop of Standard Steel Car Company. Ry. Rev., vol. 63, no. 13, Sept. 28, 1918, pp. 465-467, 9 figs. Designed for rapid erection to meet war needs; cost of construction; details of plans.

Tanks

Advice on Oil-Storage Tanks. Petroleum Rev., vol. 39, no. 836, July 27, 1918, p. 60. Manufacture of reinforced concrete tanks; expansion joints. From U. S. Bureau of Mines Bul. (Concluded)

Tank Construction (XXI), Ernest G. Beck. Mech. World, vol. 64, no. 1651, Aug. 23, 1918, pp. 90-91, 5 figs. Formulae and diagrams; side walls of rectangular tanks.

Tower Erection

Some Practical Points in Pole and Tower Erection and Support, Charles R. Harte. Elec. Ry. Jl., vol. 52, no. 12, Sept. 21, 1918, pp. 490-494, 11 figs. Particular reference to erection in marshy ground and the procedure in raising steel towers of different types.

Wind Pressure, Chimneys

Wind Pressure on Tall Chimneys. Engineering, vol. 106, no. 2752, Sept. 27, 1918, pp. 334-336, 8 figs. Observations of Professor Omori on movement to which top of a chimney is subjected by wind pressure; chimney in question is 567 ft. high.

Compression Load

The Coefficient of Safety of Reinforced and Non-reinforced Concrete Bodies Subject to Centrally and Excentrically Applied Compression Loads (Über den Sicherheitsgrad von Bewehrten und unbewehrten Betonkörpern, die auf zentrischen und exzentrischen Druck beansprucht werden), C. Bach and D. Graf. Armierter Beton, year 11, no. 5, May 1918, pp. 84-90, 4 figs. (To be continued.)

See also Wood (House Finish).

CEMENT AND CONCRETE

Cold Weather

Placing Concrete in Cold Weather. Ry. Signal Engr., vol. 15, no. 216, Sept. 1918, pp. 329-330. Rules for preparing concrete mixtures and means to protect them when freshly placed during periods of cold weather. (Portland Cement Assn. of Chicago.)

See also Railroad Engineering, Steam (Ties).

Disintegration

See Harbor Works.

Floors

On the Distribution of the Energy Stored in Reinforced Concrete Beams and Column-Supported Flat-Slab Floors, Henry T. Eddy. Jl. Franklin Inst., vol. 186, no. 4, Oct. 1918, pp. 439-448. Analytical interpretation of results obtained in 333 tests carried out by United States Bureau of Standards described in tech. paper 2.

Harbor Works

Reinforced Concrete in Harbor Works, A. F. Dyer. Can. Engr., vol. 35, no. 13, Sept. 26, 1918, pp. 277-284 and 289, 11 figs. Causes of disintegration or disruption and means of preventing them; description of two structures. Before Eng. Inst. of Can.

Paving

Concrete for Level Slope Paving. Eng. & Cement World, vol. 13, no. 6, Sept. 15, 1918, pp. 21-22, 9 figs. Results obtained in 500,000 acres reclamation project in Little River Drainage District, Mo.

Piles

Supporting Power of Concrete Pedestal Piles, Henry W. Young. Eng. & Cement World, vol. 13, no. 6, Sept. 15, 1918, pp. 17-19, 3 figs. Methods of forming and results achieved in various soil conditions.

Sections

A Note on the Determination of Excentrically Loaded Concrete Sections (Beitrag zur Bestimmung exzentrisch belasteter Eisenbetonquerschnitte), H. Paeplou. Armierter Beton, year 11, no. 5, May 1918, pp. 90-96, 2 figs.

Determination of Cross Sections of Concrete under One-Sided Compression or Tension with or without Consideration of Tensile Strength of the Concrete (Bestimmung einseitig gedrückter oder gezogener Eisenbetonquerschnitte ohne und mit Berücksichtigung der Betonzugfestigkeit), E. Elwitz. Beton u. Eisen, year 17, nos. 7-8, May 4, 1918, pp. 84-86, 3 figs.

Setting Process

The Mechanism of the Setting Process in Plaster and Cement, Cecil H. Desch. Sci. Am. Supp., vol. 86, no. 2232, Oct. 12, 1918, pp. 234-235. Attempts to examine two hypothesis and evidence induced in their support, and to indicate the nature of observed discrepancies.

CHEMICAL TECHNOLOGY

Alcohol

Manufacture of Ethyl Alcohol from Wood Waste. Engineer, vol. 126, no. 3271, Sept. 6, 1918, pp. 204-205, 1 fig. Historical resumé; description of present process; economic considerations; uses of ethyl alcohol.

Ammonia

Enormous Quantities of Ammonia Soon Available. Gas Age, vol. 13, no. 7, Oct. 1, 1918, pp. 317-318. Prospect of yield from Government synthetic plants.

The Oxidation of Ammonia, J. R. Partington. Jl. Soc. Chem. Ind., vol. 37, no. 17, Sept. 16, 1918, pp. 337R-338R, 1 fig. Form of technical converter unit for oxidation by passing ammonia and air over a heated catalyst.

Ammonium Sulphate

The New Plant at the Värta Gas Works in Stockholm, Sweden, for the Production of Ammonium Sulphate and Spirit of Salmiac (Die Neuanlagen auf dem Värtagaswerk in Stockholm zur Herstellung von schwefelsaurem Ammoniak und Salmiakgeist), O. Thümmel. Journal für Gasbeleuchtung, year 61, nos. 18 and 19, May 4 and 11, 1918, pp. 205-210, 14 figs., and pp. 217-220, 2 figs.

Atomic Weights

Revisions of Atomic Weights in 1917 (Les révisions de poids atomiques en 1917), E. Moles. Journal de Chimie Physique, vol. 16, no. 3, Sept. 16, 1918, pp. 350-376. Methods followed and results obtained in each of ten reports; list of publications on subject published in that year.

Boiling Points

Considerations on the Causes for Abnormal Boiling Points. (Considérations sur les causes des points d'ébullition anormaux), A. Berthoud. Jl. de Chimie Physique, vol. 16, no. 3, Sept. 15, 1918, pp. 245-278. Analytical research of influence of molecular association in causing the existence of abnormal boiling points with remarks on Forcrand's experiments with H_2O, ammonia and fluorhydric acid.

Copper Carbonates

The Basic Carbonates of Copper, H. Barratt Dunnicliff and Sudarshan Lal. Jl. Chem. Soc., vols. 113 and 114, no. 671, Sept. 1918, pp. 718-722. Examination of a number of samples of commercial copper carbonate showing that the statement that it has same composition as malachite is erroneous; attempt to prepare a basic copper carbonate of approximately constant composition from pure materials.

Explosives

Methods for Routine Work in the Explosives Physical Laboratory of the Bureau of Mines, S. P. Howell and J. E. Tiffany. Department of the Interior, Bureau of Mines, tech. paper 186, 63 pp., 15 tables. Precautions to be observed in storing, handling, and testing explosives; physical examination; tests with ballistic pendulum; tests in gas-and-dust gallery; rate of detonation by Mettegang recorder; conversion tables used in explosive work; list of publications.

Gasoline

Petrol From Your Own Well Gas. Petroleum World, vol. 15, no. 216, Sept. 1918, pp. 371-378, 4 figs. Facts about recovery of gasoline from natural gas by compression and refrigeration; plan of typical direct-connected compressor plant, coils and tower.

Substitute for Lamp Gasoline (Lampenbenzinersatz), A. Krieger. Journal für Gasbeleuchtung, year 61, no. 19, May 11, 1918, pp. 220-221, 1 fig.

Glass

The Significance of Glass-Making Processes to the Petrologist, N. L. Bowen. Sci. Am. Supp., vol. 86, no. 2231, Oct. 5, 1918, p. 221, 1 fig. Processes of manufacturing optical glass and factors making for inhomogeneity in glass. From Jl. of Wash. Academy of Sci.

Hydrocarbons from Coal

The Reactions of Carbonization. Times Eng. Supp., no. 528, Oct. 1918, p. 205. Conclusions drawn from experimental work in preparation of hydrocarbons from coal.

Hypophosphates

On the Preparation of Hypophosphates, R. G. Van Name and Wilbert J. Hull. Am. Jl. of

Sci., vol. 46, no. 271, Oct. 1918, pp. 587-590, 1 fig. Apparatus for preparation by oxidation of yellow phosphorus.

Leather

Recent Developments in Leather Chemistry, H. R. Proctor. Jl. Roy. Soc. of Arts, vol. 66, no. 3440, Oct. 25, 1918, pp. 747-753. Preparing skins or hides for tannage and account of some treatments.

Naphthalene

Description of Direct Determination of Naphthalene in Tar Oil and Raw Naphthalene by the Picric Acid Method (Eine Methode der direkten Naphthalin-Bestimmung in Teer, Teeröl und Rohnaphthalin durch Überführen in Pikrat), Knublauch. Journal für Gasbeleuchtung, year 61, no. 12, Mar. 23, 1918, pp. 134-137.

Determination of Naphthalene in Tars and Tar Oils, Oscar Knublauch. Gas Jl., vol. 143, no. 2888, Sept. 17, 1918, pp. 530-531. Adaptation of author's method of estimating naphthalene by direct titration of picrate with standard alkali to analysis of tars and tar oils. (From Journal für Gas Beleuchtung, vol. 61, pp. 131, 145.)

Nitrogen Oxide

Contribution to the Study of the Velocity of Oxidation of Nitrogen Oxide (Contribution à l'étude de la vitesse d'oxydation du gas oxyde d'azote), E. Briner and E. Fridori. Journal de Chimie Physique, vol. 16, no. 3, Sept. 15, 1918, pp. 279-321, 6 figs. Experimental investigation based on refrigeration of gaseous mixture.

Peat

Sulphite Peat Coal, R. W. Strehlenert. Jl. Am. Peat Soc., vol. 11, no. 4, Oct. 1918, pp. 269-274. Experiments in preparation of coal from residues of paper sulphite process. From Pulp & Paper Mag. of Can.

Petroleum

Petroleum under the Microscope, James Scott. Petroleum World, vol. 15, no. 216, Sept. 1918, pp. 378-379, 3 figs. Forms of carbon and microstructure of soot. (Continuation of serial.)

Rubber

Apparatus for Drying or Heat Treatment of Rubber. India-Rubber Jl., vol. 56, no. 14, Oct. 5, 1918, pp. 5-6, 1 fig. Apparatus in which material or articles to be treated are adapted to be supported by rotary member which conveys articles through oven.

Gauging the Degree of Vulcanization. India-Rubber Jl., vol. 56, no. 14, Oct. 5, 1918, p. 6. Operation by discontinuing supply of vulcanizing medium when rubber has expanded to an extent corresponding with degree of vulcanization desired.

Substitutes in Germany. Eng. Rev., vol. 32, no. 3, Sept. 16, 1918, pp. 71-72. Graphite economics and substitutes; regenerated rubber and substitutes; fibrous materials. (Continuation of serial.)

Synthetic Rubber. Can. Machy., vol. 20, no. 14, Oct. 3, 1918, p. 400. Substitute prepared in Germany from long continued boiling of isoprene and dimethylbutadiene.

The Rubber Industry, J. Bretland. Sci. Am. Supp., vol. 86, no. 2229, Sept. 21, 1918, pp. 178-179. Brief account of recent scientific methods. From Jl. Roy. Soc. of Arts.

Silicic Acid Gels

Silicic Acid Gels, Harry N. Holmes. Jl. Phys. Chem., vol. 22, no. 7, Oct. 1918, pp. 510-519, 4 figs. Information for preparing special silicic acid gels and report of work on effect of high concentrations of acid mixed with sodium silicate and comparative effect of weak and strong acids on silicic acid.

Sulphuric Acid

Some Data on the Contact Process of Sulphuric Acid Manufacture of the Association of Chemical Factories of Mannheim (Beiträge zur Kenntniss des Kontaktschwefelsäureverfahrens des Vereins Chemischer Fabriken in Mannheim), Hugo Ditz and Franz Kanhäuser. Zeitschrift für angewandte Chemie, year 31, no. 63, Aug. 6, 1918, pp. 149-150.

Water Gas

Discussion of the Chemical Phenomena Underlying the Formation of Water Gas (Ueber die chemischen Grundlagen der Wassergasbildung). Zeitschrift für angewandte Chemie, year 31, no. 57, July 16, 1918, pp. 137-139.

COAL INDUSTRY

Coke

On the Formation of Coke (Sur la formation de coke), Georges Charpy and Marcel Godchot. Comptes Rendus des séances de l'Académie des Sciences, vol. 167, no. 9, Aug. 26, 1918, pp. 322-324. Report of experimental work in coking carbon mixtures of different qualities.

Lignites

The Briquetting of Lignites, R. A. Ross. Iron & Steel of Can., vol. 1, no. 9, Oct. 1918, pp. 357-358. Feasibility of meeting requirements in Saskatchewan and Manitoba by utilizing prepared lignites and sub-bituminous coal.

Panel System of Mining

Suggestions for Improved Methods of Mining Coal on Indian Lands in Oklahoma, J. J. Rutledge and D. Harrington. Department of the Interior, Bureau of Mines, tech. paper, 154, 36 pp., 12 figs. Applicability of different modifications of the panel system to mining coal; list of publications on coal mining.

Screens

A New Type of Screen, M. Raymond. Coal Age, vol. 14, no. 13, Sept. 26, 1918, pp. 589-590, 3 figs. Modified form of American system of rope transmission used for coal screening.

See also Electrical Engineering (Induction Motors).

CORROSION

Iron

The Corrosion of Iron and Steel and its Prevention, Abe Winters. Can. Foundryman, vol. 9, no. 8, Aug. 1918, pp. 185-186. Important factors in process of sherardizing; conditions for commercial work.

Electrolytic Prevention

The Cumberland Electrolytic System for the Prevention of Scale and Corrosion. Elecn., vol. 81, no. 2104, Sept. 13, 1918, p. 419, 1 fig. Description of a system used by British navy and merchant marine to prevent scale and corrosion in boilers and condensers.

ELECTRICAL ENGINEERING

Air Gaps

The Reluctance of an Air Gap Having Slots in Both Opposing Surfaces, F. W. Carter. Elecn., vol. 81, no. 2103, Sept. 6, 1918, pp. 400-401, 3 figs. Comment on article by S. P. Smith appearing in Elecn. Feb. 8, 1918.

Alternators

Armature Reaction and Wave Form of a Single Phase Generator (in Japanese), G. Shimizu. Denki Gakkwai Zasshi, no. 362, Sept. 10, 1918.

Synchronising of Alternators, E. Styff. Elecn., vol. 81, no. 2098, Aug. 2, 1918, pp. 290-291, 4 figs. Abstract of article in Electrotechnische Zeitschrift.

Cables

Causes of Corrosion of Underground Electric Cables (Kabelzerstörungen in der Erde), C. Michalke. Dingler's Polytechnisches Journal, vol. 333, no. 6, Mar. 23, 1918, pp. 43-45. A somewhat general discussion.

Measurement of Power Losses in Dielectrics of Three-Conductor High-Tension Cables, F. M. Farmer. Elecn., vol. 81, no. 2098, Aug. 2, 1918, pp. 288-289, 3 figs. Describing methods used at electrical testing laboratories for measuring dielectric power losses in 10-ft. samples of three-conductor cables subjected to three-phase potential; results given for two specimens of cable, one having low and other high power loss in dielectric.

Central Stations

Reconstruction of a Two-Phase Station. Elec. World, vol. 72, nos. 14 and 17, Oct. 5 and 26, 1918, pp. 644-646, 7 figs., and 788-790, 2 figs. How some problems made necessary by rapid load developments were handled by an Iowa company. Description of furnace equipment and efficiency instruments installed in plant. (First article.)

Conductivity

A New Method for the Determination of Conductivity, Edgar Newbery. Jl. Chem. Soc., vols. 113 and 114, no. 671, Sept. 1918, pp. 701-707, 2 figs. Apparatus in which direct current is used and disturbing effects of polarization at electrodes are eliminated; values obtained for specific conductivity of solutions in mhos, at 25 deg.

Conductors, Heating of

Experiments on Heating of Conductors, Henry C. Horstmann and Victor H. Tousley. Elec. World, vol. 72, no. 15, Oct. 12, 1918, pp. 690-693, 1 fig. Application of tables which show allowable sizes of wire to use with intermittent loads such as are created by skip hoists and crane motors; economy possible in choice of conductor. (Second article.)

D. C. Motors

Operation of Direct-Current Motors in Parallel or Series, Gordon Fox. Power, vol. 48, no. 19, Nov. 2, 1918, pp. 666-668, 6 figs. Considerations leading to use of two motors in parallel are discussed.

Discharges, Disruptive

See Sparks.

Frequency Changers

Load Division Between Synchronous Frequency Changers Operating in Parallel, Quentin Graham. Power, vol. 48, no. 17, Oct. 22, 1918, 3 figs. (Second article.)

Distributing Systems

Electrical Distribution System at Hog Island Shipyard, H. W. Young. Elec. Rev., vol. 73, no. 18, Nov. 2, 1918, pp. 683-685, 5 figs. Extensive distributing system for power and lighting at world's biggest shipyard; circuits largely underground; connected load of 30,000 kw. power and 6000 kw. lighting.

Inductive Interference

Interference by High Power Lines, H. C. Don Carlos. Telephony, vol. 75, no. 17, pp. 28-30. Features of inductive interference by power lines of practical value to rural telephone companies. Before Can. Independent Telephone Convention.

Induction Motors

The Running and Maintenance of Induction Motors at Collieries, L. Fokes. Colliery Guardian, vol. 96, no. 3014, Oct. 4, 1918, pp. 701-702, 4 figs. Selection of motors; electrical considerations; pressure distribution in a star-connected stator with neutral earth—neutral insulated delta—connected stator; stator windings; type of stator best suited for colliery work.

The Slip-Ring Induction Machine (La machine asynchrone à baques), Marius Latour. Revue Générale de L'Electricité, vol. 4, no. 9, Aug. 31, 1918, pp. 291-296, 19 figs. Study of devices proposed by various inventors to increase power factor or regulate speed.

Insulation

The Protection of Electrical Apparatus, P. M. Lincoln. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 346-348. Review of methods by which integrity of electrical insulation may be secured and permanently assured.

Installation and Care of Large Electrical Apparatus for Steel Mills, O. Needham. Elec. Jl., vol. 15, No. 9, Sept. 1918, pp. 333-336, 2 figs. Suggestion in regard to insulation protection, handling, starting and operation of large motors.

Japanese Electrical Exhibition

Big Japanese Electrical Exhibition, A. E. Bryan. Elec. News, vol. 27, no. 20, Oct. 15, 1918, pp. 25-27. General description of exhibit held by Japanese Elec. Soc. to show possible markets and competition to be expected after the war

Magnetism

Normal State and Polarization in Ferro-Magnetic Materials (Normalzustand und Polarization in Ferromagnetikum), Edy Velander. Reprint from Archiv für Elektrotechnik, vol. 6, no. 12, June 22, 1918, pp. 409-437, 32 figs.

Note on a Property of Ferromagnetism (Sur une propriété du ferromagnétisme), Pierre Weiss. Revue Générale de l'Electricité, vol. 4, no. 8, Aug. 24, 1918, pp. 257-258, 2 figs. Magnetization curves of nickel at various temperatures near the Curie point. (From Comptes des Séances de L'Academie de Sciences, July 8.)

Magneto

Ignition Magneto Construction, H. R. Van Deventer. Jl. Soc. Automotive Engrs., vol. 3, no. 4, Oct. 1918, pp. 257-265, 28 figs. Review of features of magneto construction and adjustment.

On the Potential Generated in a High-Tension Magneto, E. Taylor Jones. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 212, Aug. 1918, pp. 145-169, 6 figs. Theoretical study of phenomena taking place after contacts are separated, and especially of manner in which secondary potential rises and in which its value depends upon the properties of the circuits.

Magnets

An Instrument for Testing Permanent Magnets. Automotive Ind., vol. 39, no. 12, Sept. 19, 1918, p. 505, 1 fig. Designed for testing total flux and coercive force.

Outdoor Apparatus

Housing of Outdoor Electrical Apparatus, Roger L. Evans. Quarterly of Nat. Fire Prevention Assn., vol. 12, no. 2, Oct. 1918, pp. 155-156, 1 fig. Objections to use of corrugated iron structures.

Outdoor Distribution Substation in War Times, R. E. Cunningham. Elec. World, vol. 72, no. 14, Oct. 5, 1918, pp. 642-643, 3 figs. Three-phase transformers with automatic pole-top oil switches in primary; innovation found suitable under certain conditions.

Paper, Inductive Capacity

Specific Inductive Capacity of Paper, H. C. P. Weber and T. C. MacKay. Elec. Rev., vol. 73, no. 14, Oct. 5, 1918, p. 525, 2 figs. Effect

of temperature and impregnation upon capacity. From Jl. Franklin Inst., Sept. 1918.

Polyphase Motors

Protection of Polyphase Motors with Primary Resistor Type Self-Starters. Jl. of Elec., vol. 41, no. 9, Nov. 1, 1918, pp. 407-408, 1 fig. Connections for typical resistor type self-starter with three-section resistor to give balanced starting conditions.

Rectifiers

Mercury Vapor Rectifier (Vom Quecksilberdampf-Gleichrichter). Schweizerische Bauzeitung, vol. 72, no. 13, Sept. 28, 1918, pp. 117-120, 13 figs.

Remote Control

The Remote Control of Motor Driven Pumps and Compressors, F. M. Nourse. Mun. & County Eng., vol. 55, no. 4, Oct. 1918, pp. 133-136, 14 figs. Operation of automatic motor starter.

Resistance

Direct Calculation of the Resistance of Any Number of Conductors Connected in Parallel (Calcul direct de la resistance d'un nombre quelconque de conducteurs associés en parallèle), E. Haudie. Revue Générale de l'Electricité, vol. 4, no. 10, Aug. 31, 1918, p. 297, 2 figs. Proposes improvement in methods shown in issues of Mar. 23 and June 29.

On the Rate of Change at 100 deg. cent. and at Ordinary Temperatures in the Electrical Resistance of Hardened Steel, E. D. Campbell. Iron & Steel Inst., Sept. 12-13, 1918, advance copy, paper 2, 6 pp., 2 figs. Results obtained with bars 6 millimeters square and 15 cm. long which were suspended and kept for an hour in an electrically heated furnace before being quenched in a large volume of water maintained below 10 deg. cent.

Resonance Transformer Circuits

The Power Factor in the Resonance Transformer Circuit, P. Baillie. Wireless World, vol. 6, no. 67, Oct. 1918, pp. 376-380, 3 figs. Curves showing surtension (L. Ω /R) against cos Φ for different values of K (number of semiperiods between two consecutive sparks), plotted from values computed from the formuæ derived in article.

Rotary Converters

The Design Construction and Use of Rotary Converters, C. Sylvester. Electricity, vol. 32, no. 1453, Sept. 13, 1918, pp. 479-480, 7 figs. Explanations of author's experiments illustrating principle of operation of converters. (To be continued.)

Sparks

Photographs of Electric Spark Discharges (Figures de la décharge électrique sur plâques photographiques), Usaboro Toshida. Revue Générale de l'Electricité, vol. 4, no. 8, Aug. 24, 1918, pp. 253-256, 10 figs. Interpretation of formation of Lichtenberg figures on photographic plates, from experiments under various conditions. (From Memoirs of the College of Science, Kyoto Imperial Univ., Mar. 1917.)

Storage Batteries

Thermostatic Generator Control Now Proves Success. Automotive Ind., vol. 39, no. 11, Sept. 12, 1918, p. 460, 3 figs. Saving battery life by compensation for atmospheric temperature.

Substations

The Automatic Substation Has Come to Stay, Walter C. Slade. Elec. Ry. Jl., vol. 52, no. 15, Oct. 12, 1918, pp. 651-654. Outlining present status of automatic substation.

See also Outdoor Apparatus.

Transformers

The Economical Loading of Transformer Banks. Elec. World, vol. 72, no. 16, Oct. 19, 1918, pp. 737-738, 2 figs. Giving curves which make it possible to keep most economical number of transformers in service.

Siemens-Halske Automatic Fire Extinguisher for Use in Transformer Installations (Extincteur d'incendie automatique pour cabines de transformateurs, système Siemens et Halske.) Génie Civil, vol. 73, no. 7, Aug. 17, 1918, pp. 135-136, 1 fig. Sends a large volume of carbon dioxide, gives warning and indicates place where fire started. (From Elektrotechnische Zeitschrift, May 23.)

Temperature Indicator for Transformer Winding, V. M. Montsinger, and A. T. Childs. Elecn., vol. 81, no. 2106, Sept. 27, 1918, pp. 450-451, 2 figs. Abstract of article in Genl. Elec. Rev.

Transmission Lines

Transmission-Line Construction of Duquesne Light Company, Thomas R. Hay. Elec. Rev., vol. 73, no. 17, Oct. 26, 1918, pp. 643-646, 5 figs. Difficulties met with in building a 66,000-volt line through a mountainous region.

Trouble Location

Tests for Locating Armature Trouble. Power Plant Eng., vol. 22, no. 21, Nov. 1, 1918, pp. 881-882, 3 figs. All common armature defects detected by one-man bar to bar and ground tests with voltmeter and bank of lamps.

Wiring

Insuring Against Disagreements over Wiring. Elec. World, vol. 72, no. 16, Oct. 19, 1918, pp. 735-737, 4 figs. Forms of contracts used by United Illuminating Co. of Bridgeport, Conn.

See also Factory Management (Electric Motors); Heating and Ventilation (Electric Heating); Power Plants (Power Factor); Safety Engineering (Fire Protection); Steel and Iron (Electric Steel).

ENGINEERING MATERIALS

Aeroplane Fabrics

International Aircraft Standards. Aeronautics, vol. 15, no. 253, Aug. 21, 1918, pp. 173-175, 1 fig. Specifications for unmercerized cotton aeroplane fabric (grade A); specifications for mercerized cotton aeroplane fabric (grade B); specifications for unmercerized cotton aeroplane fabric (grade B.).

Aluminum Bronze

Aluminum Bronze as an Engineering Material, Charles Vickers. Machy., vol. 25, no. 2, Oct. 1918, pp. 135-136. Difficulties in casting; use and characteristics; composition; high-tensile aluminum bronzes.

Aluminum Bronzes (Los bronces de aluminio), Jean Escard. Revista de Obras Publicas, year 66, no. 2244, Sept. 26, 1918, pp. 485-492. Their properties, manufacture and industrial utilization.

Asphalt

Standardization of Required Consistency for Asphalt, J. R. Draney. Can. Engr., vol. 35, no. 14, Oct. 3, 1918, pp. 309-310. Present variations and needed efficiency.

Bearing Metals

Conservation of Tin in Bronze Bearing Metals, G. H. Clamer. Foundry, vol. 46, no. 315, Nov. 1918, pp. 532-533. Abstract of paper at Inst. of Metals Div. of Am. Inst. of Min. Engrs., Milwaukee, Oct. 1918. Also in Am. Mach., vol. 49, no. 17, Oct. 24, 1918, pp. 773-775.

Some Notes on Babbitt and Babbitted Bearings, Jesse L. Jones. Metal Ind., vol. 16, no. 9, Sept. 1918, pp. 402-404, 5 figs. Brinell tests at progressively increasing temperatures for a lead-base and a tin-base babbitt; process and tool to give accurate and smooth surfaces to bearings. (Inst. of Metals Division of Am. Inst. of Min. Engrs., Milwaukee, October 1918.)

Boiler Plates

Causes of Failure on Boiler Plates, Walter Rosenhain and D. Hansen. Can. Machy., vol. 20, no. 14, Oct. 3, 1918, pp. 393-396, 14 figs. Effect of grain growth; alteration of crystalline structure by mechanical deformation; suggested remedies.

Copper

The Alloys of Copper and Zinc: An Investigation of Some of their Mechanical Properties, F. Johnson. Steamship, vol. 30, no. 352, Oct. 1918, pp. 82-83. Report of Brinnell hardness tests as cast and after annealing and tensile tests after annealing. Before Inst. of Metals.

The Effect of Cold Work on Copper, W. E. Alkins. Engineering, vol. 106, no. 2750, Sept. 13, 1918, pp. 283-285, 4 figs. Effect of progressive cold work upon tensile properties of pure copper. Paper before Inst. of Metals, Sept. 1918.

Gun Metal

The Influence of Impurities on the Mechanical Properties of Admiralty Gun-Metal, F. Johnston. Steamship, vol. 30, no. 352, Oct. 1918, pp. 83-84. Review of experimental results of other investigators and account of author's experiments. Before Inst. of Metals.

Hardness

The Resistance of Metals to Penetration Under Impact, C. A. Edwards. Engineering, vol. 106, no. 2750, Sept. 13, 1918, pp. 285-288, 9 figs. Including a note on hardness of solid elements as a periodic function of their atomic weights. Paper before Inst. of Metals.

Precast Concrete Lumber

Precast Concrete Lumber Proves Successful in Mine. Eng. News-Rec., vol. 81, no. 14, Oct. 3, 1918, pp. 627-629, 1 fig. Fire resistivity sought in replacing steel and wood or all-timber construction; costs about twice those of timber.

Sand

Sand and Sandstones, James Scott. Stone, vol. 39, no. 10, Oct. 1918, pp. 464-466, 3 figs. Study of minute structure and composition of sand.

Solders

Solders and Substitutes for Lead-Tin Solders, Charles W. Hill. Metal Ind., vol. 16, no. 9, Sept. 1918, pp. 412-415, 3 figs. Some notes on results of experiments conducted in Research Laboratory of Westinghouse Elec. & Mfg. Co., Pittsburgh, Pa.

Strength of Materials

The Strength of Materials, W. Cawthorne Unwin. Times Eng. Supp., no. 528, Oct. 1918, p. 219. Experimental progress in study of mechanical properties of materials, giving brief history of struggle during 18th and 19th centuries to establish the foundations of knowledge of strength of materials and touching on some recent advances in testing machines and methods. Thomas Hawksley lecture.

Tool Steel

Tool Steels. Can. Foundryman, vol. 9, no. 8, Aug. 1918, pp. 174-175. Processes followed to insure proper hardness.

See also Metallurgy; Steel and Iron.

FACTORY MANAGEMENT

Electric Motors

Care and Operation of Electric Motors in Factories, Joseph P. Collopy. Elec. Rev., vol. 73, no. 17, Oct. 26, 1918, pp. 648-662, 4 figs. Proper maintenance of special timely value; good motor location important, points on maintenance of direct-current, induction and synchronous motors.

Employment Manager

Selecting the Employment Manager, Philip Brasher. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 677-678. Requirements of ideal employment manager as seen by author.

The Employment Manager—A New Factor in Industrial Relationship, Edward D. Jones. Am. Gas Eng. Jl., vol. 109, no. 16, Oct. 19, 1918, pp. 361-364. Psychological evolution and present value of this employment. Also in Jl. Engrs. Club of St. Louis, vol. 3, no. 5, Sept.-Oct., pp. 292-301.

Factory Management

The Basis of Scientific Management, M. H. Potter. Can. Machy., vol. 20, no. 14, Oct. 3, 1918, pp. 397-399. Question of personnel in problem of management.

Graphic Control of Production

Graphic Production Control, C. E. Knoeppel. Indus. Management, vol. 56, no. 4, Oct., 1918, pp. 284-288, 5 figs. Fifteen laws of control. (Second article.)

Speeding Production by Using Graphic Meters. Elec. World, vol. 72, no. 13, Sept. 28, 1918, pp. 588-589, 6 figs. How a paper products company has installed a system of circuits in order to permit the management to check from executive office any operation going on within the plant.

Shipbuilding Methods

Shipbuilding Methods of the "Eagle" Chaser Factory. Eng. News-Rec., vol. 81, no. 18, Oct. 31, 1918, pp. 788-795, 13 figs. Hull erection divided among seven stations; extensive pre-assembly; rivets heated by electric current; launching platform; automatic platform.

Time Studies

Time Studies for Rate Setting on Gisholt Boring Mills, Dwight V. Merrick. Indus. Management, vol. 56, no. 4, Oct. 1918, pp. 289-299. (Fourth article.)

Waste

Possibilities of Salvage and Utilization of Waste, David Currie. Surveyor, vol. 54, no. 1389, Aug. 30, 1918, pp. 99-100. Work being done in U. S.; German methods; possibilities of municipal salvage. (Inst. Cleansing Superintendents.)

See also Industrial Organization; Machine Shop (Drawings); Mines and Mining (Efficiency); Power Plants (Operation).

FORGING

Axle Forging

Shaping the Front Axle Forging on the Nash Motor Car, J. Ledin. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 679-680, 5 figs. Describing design of special bulldozer die for simultaneously performing several distinct operations on automobile front-axle forging.

Shell Forging

Organizing for the Production of Forgings, J. H. Rodgers. Can. Machy., vol. 20, no. 14, Oct. 3, 1918, pp. 381-385, 7 figs. Significance of proper forging of shell in subsequent operations; new machine designed for gaging length of billets.

FOUNDRY

Casting

Casting Grey Iron Piston Rin. b. Machinery, Ellsworth Sheldon, Am Mach., vol. 49, no. 18, Oct 31, 1918, pp. 783-787, 10 figs. Description of the continuous casting of grey-iron piston rings by a machine in which advantage is taken of the action of centrifugal force upon the molten metal.

Electric Furnace

The Electric Furnace in the Steel Foundry, W. E. Moore. Can. Foundryman, vol. 11, no. 9, Oct 1918, pp 258-259. Resumé of progress attained during past few years. Before Am. Foundrymen's Assn.

Molding

A New Method of Molding Trench Mortar Shell, H. Cole Estep Foundry, vol. 46, no. 315, Nov. 1918, pp. 523-525, 6 figs. Two castings are made in each flask; jarring machines are used and production is 350 shells per day.

Modern Methods Facilitate Molding of Large Marine Engine Castings. Can. Foundryman, vol. 9, no. 8, Aug 1918, p. 178. Molding of triple-expansion engine cylinder casting.

Oil Fuel

Use of Oil Fuel in the Foundry in Urgent Exceptional Circumstances, A. E Plant. Steamship, vol. 30, no. 352. Oct. 1918, pp. 96-97. Account of installation and operation of foundry in connection with repair shops.

Sand

Bettering the Quality of Foundry Sand Mixtures, Henry B. Hanley. Can. Foundryman, vol. 11, no. 9, Oct. 1918, pp. 243-245, 5 figs. Results obtained in experimental investigation undertaken to determine mixtures of old and new sand best adapted to producing good castings. Before Am Foundrymen's Assn.

Much Depends on Securing Suitable Sand. Can. Foundryman, vol. 9, no. 8, Aug. 1918, pp. 176-177, 4 figs. Preparation of quartz and limestone sand for use in molds by Montreal company.

Steel Casting

Acid vs. Basic Steel for Castings, Edwin F. Cone. Iron & Steel of Can., vol. 1, no. 9, Oct. 1918, pp. 361-363. Uses of acid and basic castings; addition of ferro-alloys; question of oxygen; comparative physical properties; German and American steel castings.

Government Requirements for Steel Castings, E. R. Swanson. Foundry, vol. 46, no. 315, Nov. 1918, p. 538. Physical properties asked by Ordnance Department for three principal grades of steel castings are discussed.

Theory and Practice in Gating and Heading Steel Castings, Ralph H. West. Iron & Steel Inst. of Can., vol. 1, no. 8, Sept. 1918, pp. 338-347, 31 figs. Remarks on general work weighing from 1 to 500 lb., based on author's experience. Before Am. Foundrymen's Assn.

Making Ordnance Steel for the Army and Navy, John Howe Hall. Foundry, vol. 46, no. 315, Nov. 1918, pp. 535-537, Problems of steel castings manufacturers in meeting Government specifications; three essential elements of proper practice. Paper before Am. Foundrymen's Assn., Milwaukee, Oct. 1918. Also in Iron Age, vol. 102, no. 18, Oct. 31, 1918, pp. 1084-86.

See also Machinery, Special (Sand Blast Machinery).

FUELS AND FIRING

Air Preheating

Efficiency of Preheated Air. Power Plant Eng., vol. 22, no 21, Nov. 1, 1918, pp. 876-877, 3 figs. Advantages and systems of introducing preheated air to furnaces.

Ash

Fusibility of Ash from West Virginia Coals, Walter A. Selvig Power, vol 48, no 16, Oct. 15, 1918, pp. 566-567. Tables of softening temperatures of coal ash from West Virginia Coals.

Waste Due to Excess Ash in Coal. Coal Age, vol. 14, no 15, Oct. 10, 1918, pp 692-694, 4 figs. From report of J. G White Engrg. Corp. to Gano Dunn, Chairman of Engineering Committee of National Research Council.

Waste Due to Excessive Noncombustible in Coal, W. A. Shoudy. Power, vol. 48, no. 19, Nov. 2, 1918, pp. 682-683, 3 figs. From a communication to Chairman of Eng. Committee, National Research Council.

Coal

Calorific Value and Ash Yield of Coal Samples from the Same Seam, T. J. Drakeley. Colliery Guardian, vol 96, no. 3015, Oct. 11, 1918, pp. 753-794 Paper before Manchester Geological & Min. Soc., Oct 1918.

Coal Storage

Coal Storage Systems for Power Plants. Power Plant Eng., vol 22, no 18, Sept. 15, 1918, pp 750-753, 8 figs. Description of general methods of storing and reclaiming coal.

Checking Stored-Coal Temperatures Electrically, Thomas W. Poppe. Elec World, vol 72, no. 16, Oct. 19, 1918, pp. 740, 1 fig. Method of detecting incipient fires in piles of stored coal by means of electrical thermometer.

The Storage of Bituminous Coal, E. H. Stock. Power Notes, vol. 4, no 10, Oct. 1918, pp 1-3, 2 figs. Effect of storage in cost to consumer; ventilating a coal pile.

Composite Fuel

Artificial Fuel Compositions, Controlled by Industrial Fuel Corporation. Popular Engr., vol. 10, no. 1, Oct. 1918, pp. 24-25, 2 figs. Patented process to utilize accumulations of anthracite culm and slush.

Control of Heat

Automatic Heat Control for Coal Saving. Metal Worker, vol. 90, no. 16, Oct. 18, 1918, pp. 437-440. Report prepared by Committee of Heating and Ventilating Engineers by request of United States Fuel Administration. Also in Domestic Eng., Oct. 12, 1918, pp. 40-41.

Control Meters, Combustion

Combustion Control Meter. Power, vol. 48, no. 17, Oct. 22, 1918, pp. 599-600, 4 figs. Description of an arrangement of pyrometers developed by Combustion Control Co.

Diagrams of Consumption

Production and Consumption Diagrams in Central Stations, Steam and Others. (Diagrammes de production et diagrammes de consommation relatifs aux centrales électrogènes à vapeur et autres), A. Della Riccia. Revue Générale de' l'Electricite, vol. 4, no. 10, Aug. 31, 1918, pp. 299-310, 6 figs. Fuel consumption of boilers: empirical diagrams applicable to actual cases; conclusions relative to economical use of fuel. (Concluded.)

Firing Methods

Fuel Economy Made Simple, A. Bement. Power, vol. 48, no. 15, Oct. 8, 1918, pp. 524-526. Maintain a hot fire and control rate of combustion by means of draft. Appearance of fire the one comprehensive guide to fireman.

Saving Coal in Boiler Plants, Henry Kreisinger. Department of the Interior, Bureau of Mines, tech. paper 205, 24 pp., 3 figs. Instructions to firemen, engineers and owners of hand-fired plants including: methods of determining stack losses; significance of flue gas analysis; causes of large excess of air and remedy; losses from incomplete combustion; list of publications on the utilization of coal and lignite.

Fuel Conservation

Industrial Fuel Saving. Times Eng. Supp., no. 528, Oct. 1918, p. 204, 1 fig. Points out possibilities and methods.

On the Coal Economy in Steam Power Plant (in Japanese), H. Sekiguchi. Denki Gakkwai Zasshi, no. 362, Sept. 10, 1918.

Gas Firing

Installation for Burning Natural Gas under Boiler, J. J. Griffin. Natural Gas & Gasoline Jl., vol. 12, no. 8, Aug. 1918, pp. 285-286, 3 figs. Illustration and description of setting for low-pressure heating boilers.

Grates

Traveling Grate for Coke and Coke Breeze (Wanderroste für Koksgrus und Koks), Bruno Lepsien. Journal für Gasbeleuchtung, vear 61, no. 1, Jan. 5, 1918, pp. 3-8, 9 figs. Description of tests with the Pluto grate and the Nyeboe and Nissen Traveling grate for coke breeze, and the Belani and the Steinmuller grates for coke.

Half-Gas Furnaces

Half-Gas Furnaces with Undergrate Firing (Halbgasöfen mit Unterwindfeuerung), Dingler's Polytechnisches Journal, vol. 333, no. 3, Feb 9, 1918, pp. 22-23, 6 figs. Description of several German types of so-called half-gas furnaces, i.e., furnaces in which the fuel is partly gasified and partly brought to complete combustion.

Hand-Fired Furnaces

Fuel Economy in Hand Fired Boilers. Power Plant Eng., vol. 22, nos. 21 and 20, Nov. 1, and Oct. 15, 1918, pp. 878-880 and 837-839, 4 figs. Abstract of Circular no. 7, "Fuel Economy in the Operation of Hand Fired Boiler Plants," University of Illinois Engineering Experiment Station. (Second and Third article.)

Low Rate Combustion in Fuel Beds of Hand Fired Furnaces, H. Kreisinger, C. E. Augustine, and S. H. Katz. Department of the Interior, Bureau of Mines, tech. paper 139, 54 pp., 19 figs. Extension work reported in technical paper 137 which covered higher rates of combustion of 20 to 180 lb. of coal per sq. ft. of grate per hr., to rates below 20 lb. using the same apparatus and following largely equal methods.

Lignite

Burning Lignite with the Mechanical Stoker., Power House, vol. 11, no. 10, Oct. 1918, p. 306. Evaporation test made at the Government of Alberta power station with lignite slack coal.

Lignite Becomes of Importance as a Fuel Resource, S. M. Darling. Am. Gas Eng. Jl., vol. 109, no. 18, Nov. 2, 1918, pp. 415-418. Comparison of carbonized briquets for domestic service with anthracite coal; by-products from lignite. From tech. paper 178 of the United States Bureau of Mines.

Low-Grade Fuels

Low-Grade Fuels. Sci. Am. Supp., vol. 86, no. 2229, Sept. 21, 1918, pp. 191-192. Possible method of disposal. From London Times Eng. Supp.

Peat

Analysis of Canadian Peat. Jl. Am. Peat Soc., vol. 11, no. 4, Oct. 1918, pp. 253-268. From samples taken in deposits of Nova Scotia, Prince Edward Island, New Brunswick, Quebec, Ontario and Manitoba.

Inorganic Composition of a Peat and of the Plant from which it was Formed, C. F. Miller. Jl. Am. Peat Soc., vol. 11, no. 4, Oct. 1918, pp. 244-248. Brief description of both products; comparison of composition of peat and saw grass; comparison of losses of three soil forming materials in their transformation to soils.

The Peat Deposits in Minnesota, E. K. Soper. Jl. Am. Peat Soc., vol. 11, no. 4, Oct. 1918, pp. 227-243, 8 figs. Quantity, quality, and uses to which they are best adapted. Reprinted from Economic Geology, vol. 12, p. 526.

Petroleum

Petroleum as Combustible (El petroleo como combustible), J. R. Pérez. Revista de la Sociedad Cubana de Ingenieros, vol. 10, no. 9, Sept. 1918, pp. 523-531. Physical and chemical properties; refinement and uses; description of burners.

Unmined Petroleum Supply Limited, Allen Sinsheimer. Automotive Ind., vol. 39, no. 12, Sept. 19, 1918, pp. 491-493, 3 figs. Extent of supply made by United States National Museum following comprehensive survey of situation.

Powdered Coal

Powdered Coal Substituted for Fuel Oil at Seattle. Elec. Rev., vol. 73, no. 14, Oct. 5, 1918, pp. 529-531, 4 figs. Description of equipment for burning powdered coal at Puget Sound Traction Light & Power Co.'s central heating plant.

Pulverized Coal Tests Conducted at Milwaukee. Elec. Rev., vol. 73, no. 16 and 17, Oct. 19 and 26, 1918, pp. 615 and 658-659, 1 fig. Details of installation in Milwaukee. Efficiency of over 85 per cent obtained. Also in Elec. World, vol. 72, no. 16, Oct. 19, 1918, pp. 744-745; Ry. Rev., vol. 63, no. 17, Oct. 26, 1918, pp. 606-607, 2 figs; Ry Age, vol. 65, no. 15, Oct. 11, 1918, pp. 667-669, 2 figs; Power, vol. 48, no. 16, Oct. 15, 1918, pp. 556-559, 4 figs.

Smokestack Losses

Apparatus to Measure Chimney Loss and the Elements which Constitute it. (Apparell de mesure de la perte à la cheminée et des éléments constitutifs de cette perte).) Marcel Chopin. Comptes Rendus des Séances de l'Académie des Sciences, vol. 167, no. 9, Aug. 26, 1918, pp. 335-338, 2 figs. Suggests instrument registering temperature and amount of carbonic acid.

Waste Gases

Use of Waste Gases for Steam Generation, J. B. C. Kershaw. Coal Age, vol. 14, no. 13, Sept. 26, 1918, pp. 591-594. Study of progress and records of past few years.

Wood Burning

New Wood-Burning Station of Northwestern Electric Company. Elec. Rev., vol. 73, no. 15, Oct. 12, 1918, pp. 573-574, 2 figs. Details of construction and equipment.

See also Chemical Technology (Peat); Coal Industry; Foundry (Oil Fuel); Power Generation and Selection (Waste Heat); Mines and Mining (Oil Shales).

FURNACES

Electric Furnaces

The Development of Stellite, Elwood Haynes. Iron Age, vol. 102, no. 15, Oct. 10, 1918, pp. 886-888, 3 figs. Melting problems solved by Snyder Electric Furnaces which displaced gas-fired crucibles; three furnaces have capacity of over four tons in eleven hours.

Gas Ovens

Experiences with Horizontal Slot Ovens, Henry W. Douglas. Gas Age, vol. 13, no. 7,

Oct. 1, 1918, pp. 307-308. Installation of six oven benches containing three ovens each. Before Michigan Gas Assn.

See also Foundry (Electric Furnaces); Steel and Iron (Electric Steel).

HANDLING OF MATERIALS

Steel Plant

Canadian National Steel Plant. W. F. Sutherland. Can. Foundryman, vol. 9, no. 8, Aug. 1918, pp. 169-174, 13 figs. Handling of materials, arrangement of loading platform bins, installation of furnaces and other features.

HEATING AND VENTILATION

Electric Heating

Industrial Applications of Electricity. Dwight D. Miller. Elec. World, vol. 72, no. 15, Oct. 12, 1918, pp. 693-695, 2 figs. It is predicted that electric heating load will eventually surpass motor load; convenience of control of electrically generated heat results in improved product and increased production. (First article.)

Hot-Water Service

Standards of Central Station Hot Water Heating Service. Heat. & Vent. Mag., vol. 15, no. 10, Oct., 1918, pp. 31-36. Established by Public Service Commission of Indiana under date Aug. 3, 1918.

Public-School Ventilation

The Movement to Eliminate Mechanical Ventilation in New York City's Public Schools. Heat. & Vent. Mag., vol. 15, no. 10, Oct. 1918, pp. 47-49. Tests by Department of Health of classrooms in twelve rooms is basis for this action. A résumé of the tests.

Vacuum-Vapor System

Fuel Saving Heating Systems. Alfred G. King. Domestic Eng., vol. 84, no. 11, Sept. 14, 1918, pp. 390-392 and 423, 4 figs. How a vacuum-vapor heating system is installed and proves effective in fuel economy.

See also Mines and Mining (Ventilation).

HOISTING AND CONVEYING

Bonner Rail Wagon System

Freight Transportation Without Rehandling. Elec. Ry. Jl., vol. 52, no. 15, Oct. 12, 1918, pp. 658-659, 5 figs. Bonner rail wagon system aims to reduce cost and time of freight haulage by using containers on wheels which do not require warehouse facilities.

Conveyor, Coal

A Reciprocating Underground Coal Conveyor. J. F. K. Brown. Coal Age, vol. 14, no. 15, Oct. 10, 1918, pp. 682-684, 2 figs. A conveyor for use in coal beds where inclination is such that cars may be handled only with difficulty.

Cranes

Safety Code for the Operation of Electric Cranes. Power House, vol. 11, no. 10, Oct. 1918, p. 309. Formulated by Iron and Steel Elec. Engrs.

Grain-Unloading Plants

Portable Pneumatic Grain Unloading Plant. Engineer, vol. 126, no. 3266, Aug. 2, 1918, pp. 94, 95, 7 figs. Portability the interesting feature, the plant being set upon railway trucks; drawings and descriptions.

Mine-Car Dumping

Shipping Facilities at the World's Largest Coal Mine. R. W. Mayer. Coal Age, vol. 14, no. 13, Sept. 26, 1918, pp. 586-588. A mine producing 7000 tons of coal per day with mine cars dumped at rate of one every 12 sec.

Tipple

Valley Camp Coal Co.'s Tipple at Parnassus, Penn., George S. Jaxon. Coal Age, vol. 14, no. 13, Sept. 26, 1918, pp. 582-585, 11 figs. Designed to make four sizes of coal; a conveyor designed to facilitate cleaning the tracks under the tipple of spillage from the cars after the day's run.

Tractor-Trailer, Freight Handling by

Freight Handling by Tractors Found Economical. Eng. News-Rec., vol. 81, no. 16, Oct. 17, 1918, pp. 720-721, 2 figs. Tractor-trailer system replaces hand trucking and reduces costs at large L. C. L. freight station at Chicago.

See also Handling of Materials; Marine Engineering (Trimming Conveyor); Motor-Car Engineering (Crane Tractors); Transportation.

HYDRAULIC ENGINEERING

Artesian Wells

Artesian Wells for Water Supply, with Special Reference to the Artesian Wells of Wisconsin. W. G. Kirchoffer. Mun. & County Eng., vol. 55, no. 4, Oct. 1918, pp. 136-138. Velocity of flow in sandstone formations; mineral content found in ground and artesian waters.

Brazil

Water Power in Brazil. Times Eng. Supp., no. 528, Oct. 1918, p. 211. Prospects of utilization.

British Empire

Water Powers of the Empire. Can. Engr., vol. 35, no. 18, Oct. 31, 1918, pp. 383-386 and 391-392. Preliminary report of Water Power Committee appointed by Conjoint Board of Scientific Societies of Great Britain. (To be concluded.)

Dams

Calaveras Dam Slide. Report of Government Experts. D. C. Henry and C. H. Swigart. Eng. & Cement World, vol. 13, no. 7, Oct. 1, 1918, pp. 26-28, 2 figs.

Interconnected Plants

Economy of Water Effected by Intercommunication. R. H. Halpenny. Elec. World, vol. 72, no. 18, Nov. 2, 1918, pp. 828-831, 3 figs. Two hydroelectric companies, operating plants on the same stream, are interconnected through a 6000-kva. transformer; difference in load characteristics permits increasing total load with same flow of water.

Niagara Falls

Canada Rushing Huge Niagara Development as a War Conservation Measure. Eng. News-Rec., vol. 81, no. 18, Oct. 31, 1918, pp. 801-805, 9 figs. Report of construction work in digging a $8\frac{1}{2}$ mile canal around falls.

Penstock Pipes

Saving the Waste in Penstock Pipe Design. B. F. Jakobsen. Jl. of Elec., vol. 41, no. 9, Nov. 1, 1918, pp. 413-415, 2 figs. Points out manner of proportioning economically penstock pipes and transmission lines.

Turbines, Hydraulic

See Waterwheels.

Water Measurement

Measurement of Water by Means of Cipoletti Weir (Wassermessung mittels des Ueberfalls von Cipoletti). Dinglers' Polytechnisches Journal, vol. 333, no. 7, April 6, 1918, pp. 58-59. Abstract of a paper by Professor Luedecke in the German publication, Der Kulturtechniker, 1917, no. 4. Derivation of formulæ for determination of water discharge by the Cipoletti Weir. In the present article the logarithmic scale is applied and formulæ are derived.

Water Power

Fundamental Principles in the Development of Water Power. David R. Shearer. Power, vol. 48, no. 16, Oct. 15, 1918, pp. 563-565, 4 figs. Points to be considered in developing water power of a stream; explanation of fundamental calculations.

Water Supplies

The Development of Water Supplies for Rural Communities in Saskatchewan. E. L. Miles. Eng. & Contracting, vol. 50, no. 11, Sept. 11, 1918, pp. 254-255, 3 figs. Supply from springs; reservoirs; instructions for the construction of dams; dugout type of reservoir. (Engrg. Inst. of Canada.)

Waterwheels

Tests on a 715-Hp. High Speed Water Turbine. (Ueber Leistungsversuche an einer schnell aufenden Wasserturbine von 715 PS), W. Schmid. Schweizerische Bauzeitung, vol. 72, no. 14, Oct. 5, 1918, pp. 129-131, 4 figs.

Waterwheel Types and Settings. David R. Shearer. Power, vol. 48, no. 19, Nov. 2, 1918, pp. 670-672, 11 figs. Various forms of waterwheels and turbines with regard to direction of flow of water, position of shaft and casing of wheel.

Waterworks

New Water Works in the City of Trier (Das neue Grundwasserwerk der Stadt Trier im Moselthal bei Kenn), Wahl. Journal für Gasbeleuchtung, year 61, nos. 7, 8, 9 and 10, Feb. 16 and 29, Mar. 2 and 10, 1918, pp. 77-81, 8 figs., pp. 85-89, 3 figs., pp. 100-104, 8 figs., and pp. 111-117, 6 figs. Extensive description with illustrations.

The Economics of Public Utilities Extensions. J. W. Ledoux. Am. City, vol. 19, no. 4, Oct. 1918, pp. 293-295. Discussion of proper relation of estimated revenue to estimated cost of water-works extension or improvement.

See also Mines and Mining (Water in Mines); Power Plants (Hydroelectric); Safety Engineering (Water Mains.)

INDUSTRIAL ORGANIZATION

Accounting

Cost Accounting to Aid Production. C. Charter Harrison. Indus. Management, vol. 56, no. 4, Oct. 1918, pp. 273-282, 2 figs. Application of scientific management principles. (First article.)

Relation of Statistics and Accounting in Industrial Management. Milton B. Ignatius. Indus. Management, vol. 56, no. 4, Oct. 1918, pp. 312-315. Tells what matters should have statistical study and gives numerous practical points in regard to organizing work and selecting statistician.

Drafting Room

Simple Drafting Room Methods. G. F. Hamilton. Indus. Management, vol. 56, no. 4, Oct. 1918, pp. 301-304, 15 figs. How a machine building plant systemizes its drafting work.

Inspection

Inspection and Quality Control. F. E. Merriam. Indus. Management, vol. 56, no. 4, Oct. 1918, pp. 305-311, 5 figs. Practical application of underlying principles; outlines organization of an inspection department, points out divisions of work, treats of selection and training of inspectors, tells how to uphold standards, and gives suggestions on selection and application of inspection gages.

Reconstruction

Reconstruction Problems from an Engineering Standpoint. Jl. Engrs. Club of St. Louis, vol. 3, no. 5, Sept.-Oct. 1918, pp. 305-308. Suggestions to engineering organizations.

INTERNAL-COMBUSTION ENGINEERING

Constant-Pressure Engines

Fuel Admission Valve of Constant Pressure Internal Combustion Engines (Das Brennstoffventil der Gleichdruckmaschine). Dinglers polytechnisches Journal, vol. 333, no. 10, May 18, 1918, pp. 85-86, 3 figs.

(See also Oil Engines.)

Diesel Engines

Operation of Diesel Engines in China. Harold B. Wilson. Motorship, vol. 3, no. 11, Nov. 1918, pp. 9-10, 4 figs. Data concerning operation of five different Diesel makes under author's charge. (To be continued.)

The Diesel Engine; its Fuels and its Uses. Herbert Haas. Department of the Interior, Bureau of Mines, bul. 156, petroleum technology no. 44, 130 pp., 73 figs. Details of three general types, explosion, Diesel and Sabathé; methods permitting use of coal-tar and coal-tar oils; classification, composition and properties of fuels; formulae for computing fuel cost; examples of successful use of Diesel engines; selected bibliography. Also in Gas Eng., vol. 20, no. 11, Nov. 1918, pp. 513-519, 4 figs.

The True Status of Diesel Engines. J. C. Shaw. Marine Rev., vol. 48, no. 10, Oct. 1918, pp. 449-450. Remarks on rational design of an oil engine (Aug. issue) in reference to statements about ignition disturbances.

Gas Engines

1500-hp. Gas Blowing Engine. Engineer, vol. 126, no. 3271, Sept. 6, 1918, pp. 207, 4 figs. Principally drawings of engine.

Governors

The Design of Governors, with Special Reference to Small Diesel Engines. Arthur B. Lakey. Proc. Engrs. Soc. of Western Pa., vol. 34, no. 6, July 1918, pp. 461-481, 12 figs. and (discussion) pp. 482-488, 1 fig. Points out shortcuts in design and adjustment of certain types of centrifugal governors, and shows need of certain auxiliary apparatus to secure improved smoothness of running in the case of Diesel engines of small power, or with only small flywheels.

Governing

Investigation of Gas Engine Governing (Untersuchung einer Gasmaschinenreglung). A. Gramberg. Dinglers Polytechnisches Journal, vol. 333, no. 7, Apr. 6, 1918, pp. 53-55, 5 figs. Data of an extensive experimental investigation.

High-Speed Engines

High-Speed Internal Combustion Engines. Harry R. Ricardo. Mech. World, vol. 64, nos. 1645, 1649 and 1650, July 12, Aug. 9, and Aug. 16, 1918, p. 17, 7 figs., p. 69, 1 fig., and pp. 81-82, 6 figs. July 12: Comparative wear and tear of slow- and high-speed engines. Aug 9: Factors affecting volumetric efficiency and possibilities of increasing it, theories explaining detonation or "pinking." (Northeast Coast Instn. of Engrs. & Shipbuilders.)

Indicator Diagrams

The Theoretical Indicator Diagram. O. A. Malychevitch. Automotive Ind., vol. 39, no. 12, Sept. 19, 1918, pp. 499-502, 2 figs. Method of predetermining gas temperatures and pressures for various points in engine cycles from chemical composition of charge and physical properties of components.

Oil Engines

Faults in the Design of Some Surface Ignition Oil Engines, W. J. Woodcock. Motorship, vol. 3, no. 11, Nov. 1918, p. 16, 1 fig. An operator's idea of an improved motor.

New Type of Marine Oil Engine. Int. Mar. Eng., vol. 23, no 10, Oct. 1918, pp. 563-566, 6 figs. Two-cycle Weiss engine; simple injection system. Description of engine and discussion of scavenging.

Oil Engine Sprayers or Pulverizers. A. H. Goldingham and C. T. O'Brien. Motorship, vol. 3, no. 11, Nov. 1918, pp. 14-15, 5 figs. Details of various types of injection valves. (Concluded from Sept. issue.)

The Heavy Oil Engine, Charles E. Lucke. Int. Mar. Eng., vol. 23, no. 10, Oct. 1918, pp. 579-583. Discussion of factors to be considered in design; small demand as yet for heavy oil types; future possibilities. Paper before Engrs. Club of Philadelphia, Jan. 1918.

The Heavy Oil Engine, Chas. E. Lucke. Popular Engr., vol. 10, no. 4, Oct 1918, pp. 17-18 and 22. Presentation of ideas involved in development up to present time and consideration of possibility of change in near future. Before Engrs. Club of Phila.

Power Output

The Increase of Power Output, Emil Schimanek. Aerial Age, vol. 8, no. 4, Oct. 7, 1918, pp. 170-173 and 193, 20 figs. Increase of power output in internal combustion by (1) increasing thermal efficiency, (2) increasing number of working strokes in unit-time, or (3) increasing air charge in working cylinders. Translated from Zeitschrift des Vereines Deutscher Ingenieure.

Pulverizers

See Oil Engines.

Sleeve-Valve Engine

Tests of a Sleeve Valve Engine. Automotive Ind., vol. 39, no. 12, Sept. 19, 1918, pp. 494-498, 12 figs. Monograph diagram, horsepower and torque curves.

Sprayers

See Oil Engines.

See also Marine Engineering (Motor Ships.)

LABOR

Aliens

See Americanization.

Americanization

Making Americans on the Railroad. Samuel Rea. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 673-676. Methods adopted and results achieved in persuading and fitting foreign-born employees of Penn. R. R. to become loyal and useful citizens.

Apprenticeship

Cooperative Management—The Apprentice, Arthur F. Johnson. Int. Mar. Eng., vol. 23, no. 10, Oct. 1918, pp. 567-568. Apprentice a vital essential in industry; should be given liberal education; freedom of shop important for his rounded education.

Bonus System

Fuel Bonuses in Central Stations (Prime à l'économie de charbon dans les stations centrales thermiques), L. Conge. Revue Générale de l'Electricité, vol. 4, no. 10, Aug. 31, 1918, pp. 319-320, 1 fig. How a bonus system may be established and employees made to coöperate in the economization of fuel.

Cooperation

The Babson Conference on Coöperation. Am. Mach., vol. 49, no. 17, Oct. 24, 1918, pp. 749-752. Account of conference, fifth annual, held at Wellesley Hills, Mass., Sept. 1918, on profit-sharing, labor turnover and efficiency, United States Employment Service, and experience in collective bargaining and in dealing with unions.

Employee Representation

Bethlehem Plan of Employee Representation. Iron Age, vol 102, no. 17, Oct. 24, 1918, pp. 1020-1022, 2 figs. Monthly committee meetings and annual conferences to consider wages, working conditions, housing and all other questions of mutual interest.

Housing

Lodging House for Thirty Men Costs $11,000 Elec. Ry. Jl., vol. 52, no. 14, Oct. 5, 1918, pp. 615-616, 5 figs. Details of a lodging house built by Connecticut Co. at Waterbury, Conn

Soldiers Discharged

The Employment of Discharged Soldiers Times Eng. Supp., no. 528, Oct. 1918, pp. 201-202. Methods by which engineering trades may help to solve problem.

Supervision

The Mechanical Department Supervision Problem, Frank McManamy. Ry. Age, vol 65, no. 17, Oct. 25, 1918, pp. 729-731. Dilution of quality of labor has increased need of more and better supervision. Abstract of paper before New York Railroad Club.

Training

How Best to Educate the Road Foreman, the Engineer and the Fireman, Frank J. Barry. Proc. Central Ry. Club, vol. 26, no. 4, Sept. 1918, pp. 442-448 and (discussion) pp. 448-466. Consideration of different methods and observations on matters having bearing on character of results education is likely to produce.

Training Minor Executives in a Large Shoe Factory, Roy Willmarth Kelly. Indus. Management, vol. 56, Oct. 1918, pp. 316-319, 2 figs.

Training School for Machine Operators. Iron Age, vol. 102, no. 17, Oct. 24, 1918, pp. 1011-1012, 2 figs. Special department at Timken plant gives better results than breaking in in regular departments.

Turnover

Keeping Track of Labor Turnover, E. H. Fish. Automotive Ind., vol. 39, no. 11, Sept. 12, 1918, pp. 445-446. Suggests careful compilation and analysis of turnover records in plants where semi-skilled men must be trained to meet labor needs.

Women

Introducing Woman Labor into the Shop, M. C. Hobart. Am. Mach., vol. 49, no. 17, Oct. 24, 1918, pp. 769-770. Experience of a Chicago firm in this new departure.

Manufacture by Women. Times Eng. Supp., no. 528, Oct. 1918, p. 217. Account of exhibitions of women's work formed by Ministry of Munitions through Technical Section of its Labor Supply, at Liverpool.

Putting Women Into the Machine Shop, F. L. Prentiss. Iron Age, vol. 102, no. 15, Oct. 10, 1918, pp. 892-896, 2 figs. Short probationary period successful in Cleveland plants; qualities in which women excel; reduced labor turnover.

Solving New Haven's Man-Power Problem, Charlton L. Edholm. Am. Mach., vol. 49, no. 16, Oct. 17, 1918, pp. 721-723, 2 figs. Account of effort to secure services of women of New Haven in munitions shops of Winchester Repeating Arms Co.

The Demand for and Supply of Women Workers. Automotive Ind., vol. 39, no. 12, Sept. 19, 1918, pp. 490-491. Contrast between percentages of American and English women now employed.

The Renumeration of Male and Female Labor. Eng. Rev., vol. 32, no. 3, Sept. 16, 1918, pp. 68-69. Discussion of relative efficiencies of male and female labor in the light of extensive experience in engineering shops.

Women in Central Station Work, J. W. Alexander. Jl. of Elec., vol. 41, no. 9, Nov. 1, 1918, pp. 392-393, 5 figs. Account of work being done by women as power plant operators and meter readers.

LEGAL

Building Law

Puzzling Variations in Important Building-Law Clauses, R. Fleming. Eng. News-Rec., vol. 81, no. 13, Sept. 26, 1918, pp. 579-581. Requirements as to stresses; specified wall thickness often wasteful; wind bracing neglected; interesting special features.

See also Electrical Engineering (Wiring); Safety Engineering (Dangerous Tools), (Grinding Tools.)

LIGHTING

Dispersion of Light

Dispersion of Light as a Means of Reducing the Surface Brightness of Artificial Illuminants (Die Streuung des Lichtes als Mittel zur Verringerung der Flächenhelle künstlicher Lichtquellen), N. A. Halbertsma. Dingler's polytechnisches Journal, vol. 333, no. 9, May 4, 1918, pp. 76-77, 2 figs.

Better Lighting of Glass Works and Potteries, F. H. Bernhard. Elec. Rev., vol. 73, no. 15, Oct. 12, 1918, pp. 567-572, 6 figs. Eighth of a series of articles on improvement in lighting in the industries.

Lighting of Rubber-Goods Factories, F. H. Bernhard. Elec. Rev., vol. 73, no. 17, Oct. 26, 1918, pp. 653-657, 5 figs. Ninth of a series on lighting in industries.

Factory Lighting

Terminal Shop and Classification Yard Lighting. Ry. Rev., vol. 63, no. 18, Nov. 2, 1918, pp. 625-627, 5 figs. General discussion of modern shop and yard lighting systems through the use of the flood system. Committee report before Convention of Assn. of Ry. Elec. Engrs., by J. E. Gardner.

House Lighting

The Lighting Ration in Practice. Illuminating Engr., vol. 11, no. 7, July 1918, pp. 177-181. Suggests how lighting rations under household fuel and lighting order may be expected to apply to two typical houses, having respectively six and twelve rooms.

Illuminants

Experimental Comparison of the Lighting Efficiency of Various Artificial Sources of Illumination (Zur Beurteilung der Beleuchtungswirkung künstlicher Lichtquellen), W. Bertelsmann. Journal für Gasbeleuchtung, year 61, no. 6, Feb. 9, 1918, pp. 61-64.

Lighting Economies

Possible Wartime Lighting Economies. Elec. News, vol. 27, no. 21, Nov. 1, 1918, pp. 23-26. Report of committee on war service of the Illuminating Eng. Soc.

Mantle Lights

A Physical Study of the Welsbach Mantle, H. E. Ives, E. F. Kingsbury, and E. Karrer. Jl. Franklin Inst., vol. 186, no. 4, Oct. 1918, pp. 401-438, 15 figs. Details of theory of ordinary mantle, and application of Rubens methods, as well as other new methods, to mantles composed of other oxides and oxide mixtures. (To be continued.)

Urges Use of Pilots with Mantle Lamps as Fuel Conservation Measure. Am. Gas Eng. Jl., vol. 109, no. 16, Oct. 19, 1918, pp. 367-371. Report of Illuminuating Eng. Soc. giving rules limiting use of artificial light to minimum necessary number of hours per day and promoting most efficient use of artificial light during those hours.

Photometers

Improvements in the Spherical Photometer, R. von Voss. Elecn., vol. 81, no. 2104, Sept. 13, 1918, pp. 418-419, 1 fig. Abstract of an article in the "Elektrotechnische Zeitschrift," no. 52, 1917.

Street Lighting

War-Time Street Lighting Economy. J. R. Cravath. Am. City, vol. 19, no. 4, Oct. 1918, pp. 303-304, 2 figs. Indicates where reductions can be made. From compilations of data and opinions of illuminating engineers throughout the country presented before Illum. Engrs. Soc.

See also Standards and Standardization (Lamp Voltages.)

LUBRICATION

Cutting Lubricants

Cutting Lubricants. Times Eng. Supp., no. 528, Oct. 1918, p. 218. Memorandum issued by Department of Scientific and Industrial Research, prepared by a committee of department in connection with a survey of field for research on lubricants and lubrication.

Explosion Engines

Lubrication of Explosion Engines. Petroleum World, vol. 15, no. 216, Sept. 1918, pp. 380-381. Action of oil and suggestions on selection of lubricant. (Concluded.)

Marine Engines

The Lubrication of Marine Engines. Shipbuilding & Shipping Rec., vol. 12, no. 12, Sept. 19, 1918, pp. 277-278. Principles to be followed regarding place of application of oil; considerations on frequency and pressure.

Viscosity of Oils

Viscosity and Constitution of Lubricating Oils. Sci. Am. Supp., vol. 86, no. 2232, Oct. 12, 1918, p. 240. Review of conclusions obtained by various experimenters.

MACHINE DESIGN

Cams

Cam Profiles (II). Wm. Ker Wilson. Mech. World, vol. 64, no. 1649, Aug. 9, 1918, pp. 66-67, 7 figs. Displacement curves of cam giving simple harmonic motion to roller and of cam giving uniform acceleration to roller.

MACHINE PARTS

Bearings

Life of Ball Bearings (Ueber Lebensdauer von Kugellagern), Henry Gärtner. Dingler's Polytechnisches Journal, vol. 333, no. 5, Mar. 9, 1918, pp. 35-38, 4 figs. Safe loads on ball bearings and the life of ball bearings under various conditions of loading and maintenance.

Roller Bearings for Machine Shop Equipment, Edward K. Hammond. Machy., vol. 25, no. 2, Oct. 1918, pp. 115-122, 14 figs. (Fourth article.)

The "Dragon" Ball Bearing. Can. Machy., vol. 20, no. 17, Oct. 24, 1918, pp. 475-476, 4 figs. Double row ball bearings, manufactured in standard single row widths, in each instance containing approximately double the number of balls of corresponding single row bearing, the two rows of balls being staggered in relation to each other.

Bolts

On the Strength of Bolts in Aeroplane Structures, John Case. Aeronautics, vol. 15, no. 253, Aug. 21, 1918, pp. 158-162, 8 figs. Analytical computation of distribution of load between several bolts bearing same load in (1) strap joint under direct load, (2) single lateral force divided between several bolts, (3) when there is bending. (Concluded.)

Stress Distribution in Bolts and Nuts, C. E. Stromeyer. Int. Mar. Eng., vol. 23, no. 10, Oct. 1918, pp. 589-591, 4 figs. Character and analysis of strains in butt straps; instrument for ascertaining difference in thread pitch. Paper before Inst. of Naval Architects, London, March 1918.

Flywheels

Disastrous Flywheel Explosion at Chicago. Power, vol. 28, no. 15, Oct. 8, 1918, pp. 516-519, 6 figs. Details of an accident to a 24 by 42-in. 500 hp. Corliss engine.

Keyways

Figuring Keyways on Shafts, John Havekost. Machy., vol. 25, no. 2, Oct. 1918, pp. 152, 1 fig. A collection of formulæ.

Sprockets

Sprocket Design, Theory and Practice, Wiley M. Free. Machy., vol. 25, no. 2, Oct. 1918, pp. 147-150, 4 figs. Factors controlling designing of sprockets for malleable chain drives, and action of chain on driving and driven sprockets under different conditions.

See also Standards and Standardization (Gearing.)

MACHINE SHOP

Balancing

Methods of Balancing Rotors, C. C. Brinton. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 349-352, 9 figs. Static and dynamic balances; balancing machines.

Chain Cables

Memorandum Regarding the Manufacture of Cast-Steel Chain Cables. Steamship, vol. 30, no. 352, Oct. 1918, pp. 90-91. Report of Committee of Lloyd's Register; summary of previous attempts and present position; testing of cast-steel chains. Also in Practical Engr., vol. 58, no. 1643, Aug. 22, 1918, pp. 91-92. (To be continued.)

Chain Making

The Manufacture of a Diamond Transmission Chain, J. V. Hunter. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 643-647, 13 figs. Description of some automatic and semi-automatic machines used in manufacture of transmission chain.

Drawings

A Study of Drafting Room Errors, R. Fleming. Eng. & Contracting, vol. 50, no. 17, Oct. 23, 1918, pp. 378. Most common and most expensive errors made in structural drafting.

Representation of Screw Threads and Dimensioning. Can. Machy., vol. 20, no. 9, Sept. 5, 1918, pp. 291-294, 27 figs. Rules for dimensioning drawings.

Gages

Developing a Gaging System for Small Arms and Heavy Ordnance, Erik Oberg. Machy., vol. 25, no. 2, Oct. 1918, pp. 93-107, 9 figs. First of a series describing principles involved and procedure followed in developing gaging systems for interchangeable manufacture. Based upon experience of Pratt & Whitney Co. in furnishing gaging equipment for small arms and heavy ordnance work.

Rules for Computing Gage Tolerances, D. Douglas Demarest. Indus. Management, vol. 56, no. 4, Oct. 1918, pp. 332-334, 3 figs. Three simple rules show how to compute overall length, mean length and mean depth of finish.

Gage Making

Gage Making in a Shell Plant, Franklin D. Jones. Machy., vol. 25, no. 1, Sept. 1918, pp. 1-6, 19 figs. Sixth of series of articles describing methods employed in a plant making United States 75-mm. shell.

Gear Cutting

Electric-Railway Motor Pinion Making. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 648-650, 7 figs. Describing various steps in manufacture of gears and pinions for electric-railway motors.

Heat Treatment

Annealing Cold-Rolled Aluminum Sheet by Abbreviated Exposures at Various Temperatures, Robert J. Anderson. Page's Eng. Weekly, vol. 33, no. 734, Oct. 4, 1918, pp. 160-161. Report of experiments. Before Inst. of Metals.

Hosiery-Machine Making

Making Hosiery-Machine Parts, Robert Mawson. Am. Mach., vol. 49, no. 16, Oct. 17, 1918, pp. 709-710, 5 figs. Sequence of operations in milling certain members of hosiery machines as practised by Hemphill Mfg. Co., Pawtucket, R. I.

Irregular-Shaped Work

Generating Cams and Irregular-Shaped Work, Douglas P. Hamilton. Am. Mach., vol. 49, no. 17, Oct. 24, 1918, pp. 737-740, 12 figs. Outlining possibilities of producing in gear shaper and on a commercial basis cams and other irregular forms.

Moving-Picture-Machine Making

Making a Moving Picture Machine, M. E. Hoag. Am. Mach., vol. 49, nos. 16 and 17, Oct. 17 and 24, 1918, pp. 718-720, 16 figs., 759-761, 10 figs. The light shutter. (Second and third article.)

Screw Work

Production Problems of Aircraft Bolts, Screws and Nuts, W. H. Sheahan. Aviation, vol. 5, no. 6, Oct. 15, 1918, pp. 363-365, 4 figs. Gaging machines.

Tractor Manufacture

Manufacturing the Caterpillar Tractor, Frank A. Stanley. Am. Mach., vol. 49, nos. 17 and 18, Oct. 24 and 31, 1918, pp. 745-747, 5 figs., and 801-804, 9 figs. General features. (First and second article.)

Truck Making

Assembling the Liberty Truck, M. E. Hoag. Am. Mach., vol. 49, no. 18, Oct. 31, 1918, pp. 813-815, 11 figs. Description of methods used in a Western factory.

Welding

Cutting Test Pieces from Shells. Can. Foundryman, vol. 9, no. 8, Aug. 1918, p. 183, 1 fig. General details of machine operating by oxy-acetylene torch.

Fusion Welding Fallacies, S. W. Miller. Machy., vol. 25, no. 2, Oct. 1918, pp. 123-124, 2 figs. (Fourth article.)

New Work for the Welding Engineer, C. W. Brett. Aeronautics, vol. 15, no. 253, Aug. 21, 1918, pp. 170-171, 4 figs. Shows application of welding to an aluminum airplane engine crankcase and to a cast-iron cog wheel.

Practical Data Upon Electrical Spot Welding, G. A. Hughes and R. H. Pool. Elec. World, vol. 72, no. 16, Oct. 19, 1918, pp. 742-744, 2 figs. Power consumption, strength of welds and speed with which welds can be made determined for various kinds of plates.

Selection and Application of Electric Arc Welding Apparatus, A. M. Caudy. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 337-346, 25 figs. Requisites for alternating-current arc welding and direct-current arc welding; constant current versus constant potential generators; protective equipment and accessories; welding principles; selection of electrodes; gas versus electric arc.

Some Notes on the Resistance Method of Electric Welding, G. W. Stubbings. Mech. World, vol. 64, no. 1654, Sept. 13, 1918, p. 124. Manner of applying electric supply to weld in case of direct current and also in case of alternating current.

The Oxy-Acetylene Process for Welding Boiler-Plate, H. A. Boyd. Mech. World, vol. 64, no. 1649, Aug. 9, 1918, pp. 69-70. Result of tests made of three pieces taken from new boiler-plate. (Cal. Safety News.)

The Practice of Oxy-Acetylene Welding, J. T. Morton. Aeronautics, vol. 15, no. 253, Aug. 21, 1918, pp. 165-169, 12 figs. Suggestions regarding selection of burners, determination of correct proportions of burning gases in flame and other details of process.

See also Engineering Materials (Tool Steel); Railroad Engineering, Steam (Shops); Safety Engineering (Punch Presses); Steel and Iron (Quenching); Machinery, Special (Sand-Blast Machinery).

MACHINE TOOLS

Second-Hand Tools

The Buying of Second-Hand Machine Tools, Donald A. Hampson. Can. Machy., vol. 22, no. 16, Oct. 17, 1918, pp. 466-467. Importance of determining age of machine and its serial number.

Sine-Bar Fixture

Sine-Bar Fixture. Machy., vol. 25, no. 2, Oct. 1918, pp. 145-146, 4 figs. Drawings of fixture and explanation.

See also Machine Shop (Moving-Picture-Machine Making), (Hosiery-Machine Making).

MACHINERY, SPECIAL

Sand-Blast Machinery

Automatic Shell Cleaning Cabinet Sand-Blast. Can. Foundryman, vol. 11, no. 9, Oct. 1918, p. 265, 4 figs. Machine designed to provide continuous operation for cleaning 155-mm. shells with direct high pressure.

How to Select Suitable Sand-Blast Equipment, H. D. Gates. Foundry, vol. 46, no. 315, Nov. 1918, pp. 539-545, 12 figs. Results and operation costs should carry greater weight than first price; description of various types. Paper before Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

MARINE ENGINEERING

Boat Lowering

Boat Lowering Appliances, J. R. Hodge. Tran. Inst. Marine Engrs., vol. 30, paper 237, Aug. 1918, pp. 123-127, 4 figs. and (discussion), pp. 127-136. Discusses merits of gear for lowering and disengaging of boats from vessels in emergencies at sea.

Boilers

Sediment in Marine Boilers, W. R. Austin. Steamship, vol. 30, no. 352, Oct. 1918, pp. 94-95, 1 fig. Points out where risk of accident generally arises.

Cargo Gear

Some Insufficiently Considered Details of Ship Construction and Equipment, C. Waldie Cairns. Int. Mar. Eng., vol. 23, no. 10, Oct. 1918, pp. 570-575. Analysis of conditions of yard management; details of ship equipment criticized; stresses on cargo gear. Paper before northeast Coast Inst. of Engrs. & Shipbuilders, Newcastle-upon-Tyne.

Concrete Ships

Concrete Barges Built True to Design Dimensions. Eng. News-Rec., vol. 81, no. 16, Oct. 17, 1918, pp. 704-707, 6 figs. Special spacer fix wall thickness and rod location; account of yard started at Providence, R. I.

Method of Building Concrete Barges at Yard of Aberthaw Construction Co. Eng. & Contracting, vol. 50, no. 17, Oct. 23, 1918, pp. 383-384, 3 figs. Description of work in progress at Fields Point, R. I. Also in Int. Mar. Eng., vol. 23, no. 10, Oct. 1918, pp. 584-585, 3 figs.

Novel Method of Constructing Concrete Vessels, R. N. Stroyer. Shipbuilding & Shipping Rec., vol. 12, no. 14, Oct. 3, 1918, pp. 327-330, 5 figs. Description of writer's patented system which aims to reduce number of joints to minimum.

Standard Concrete Barge for Use on the New York State Barge Canal. Int. Mar. Eng., vol. 23, no. 10, Oct. 1918, pp. 586-588, 6 figs. Authorized design for service on state canal; unusual refinement of concrete used; plans and specifications.

The Building of Reinforced Concrete Ships. Engineering, vol. 106, no. 2744, Aug. 2, 1918, pp. 114-115, 4 figs. Illustrations taken at various stages of work showing reinforcing, etc.

Diving Machinery

Sisson Diving Machine. Steamship, vol. 30, no. 352, Oct. 1918, pp. 79-80, 2 figs. Oval shaped machine 9 ft. long, 7 ft. 6 in. in diameter, 9 tons weight, with pair of propellers on bottom for moving up and down and two on side for propelling forward or back.

Motorships

Motor Ship "Santa Margarita." Steamship, vol. 30, no. 352, Oct. 1918, pp. 91-92. Detail of ship equipped with Diesel Engines.

Propellers

Screw Propellers. Shipbuilding & Shipping Rec., vol. 12, no. 14, Oct. 3, 1918, pp. 331-332, 1 fig. Shape of blades and patent propellers; propeller immersion and efficiency. (Concluded.)

Rivetless Ships

See Welded Ships.

Salvage

Thirteen-Thousand-Ton Vessel Righted by Rolling and Lifting. Eng. News-Rec., vol. 81, no. 17, Oct. 24, 1918, pp. 764-767, 8 figs. Raising of "St. Paul" after settling on its side between New York piers.

Signaling

A Method of Avoiding Collision at Sea, J. Joly. Proc. Roy. Soc., vol. 94, no. A664, Aug. 1, 1918, pp. 547-560, 4 figs. Based on synchronized signals transmitted in different media, no other communication being necessary between the ships beyond signals.

Smoke System, Yarrow

The Yarrow Anti-Submarine Smoke System. Engineer, vol. 126, no. 3272, Sept. 13, 1918, pp. 218-219, 5 figs. Description of a smoke screen system of protection.

Standardized Ships

German Views on Standard Vessels, W. Kreul. Shipbuilding & Shipping Rec., vol. 12, no. 9, Aug. 29, 1918, pp. 212-213. Standardization as a means for accelerating building of ships; constructional parts and processes. Translated from Stahl und Eisen.

Standardized Concrete Ships in the United States. Shipbuilding & Shipping Rec., vol. 12, no. 9, Aug. 29, 1918, pp. 210-212. Alternative arrangement of concrete distributing plant.

Standardized Ships May be Permanent. Nautical Gaz., vol. 94, no. 17, Oct. 26, 1918, p. 224, 1 fig. Advantages and drawbacks of vessels of uniform type. From Engineering, London.

Stresses

Investigation of the Shearing Force and Bending Moment Acting on the Structure of a Ship, Including Dynamic Effects, A. M. Robb. Int. Mar. Eng., vol. 23, no. 10, Oct. 1918, pp. 592-593, 3 figs. Paper before Instn. of Naval Architects, London, March 1918.

Trimming Conveyor

Portable Automatic Trimming Conveyor. Colliery Guardian, vol. 96, no. 3012, Sept. 20, 1918, pp. 601-602, 6 figs. Description of an automatic conveyor used for trimming coal in bunkers on shipboard.

Valves, Kingston

Hand Regulated Valves. Mech. World, vol. 64, no. 1650, Aug. 16, 1918, pp. 78-79, 7 figs. Kingston valves of ships as examples of construction where element of safety is predominant above other considerations. (Concluded from Aug. 2.)

Welded Ships

The British Welded-Steel Motorship. Motorship, vol. 3, no. 11, Nov. 1918, pp. 22-23, 5 figs. Method of operation of novel type of oil engine installed in a merchant vessel.

See also Factory Management (Shipbuilding Methods); Safety Engineering (Fire Protection); Corrosion (Electrolytic Prevention).

MATHEMATICS

Bessel Functions

The Addition Theorem of the Bessel Functions of Zero and Unit Orders, John R. Airey. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 213, Sept. 1918, pp. 234-242. Form of addition theorem of $J_n(x)$ functions in which one of the terms is a root of a Bessel or Neumann function of zero or unit order.

A Diffraction Problem, and an Asymptotic Theorem in Bessel's Series, R. Hargreaves. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 212, Aug. 1918, pp. 191-199. Form to solve problem in two dimensions offered as more convenient than Sommerfeld's; also solution in definite integral transformed directly to series of Bessel's functions and trigonometrical functions of problem in three dimensions, which arises when plane of incident wave is not parallel to edge of barrier.

Collineation Groups

A Collineation Group Isomorphic with the Group of the Double Tangents of the Plane Quartic, C. C. Bramble. Am. Jl. of Mathematics, vol. 40, no. 4, Oct. 1918, pp. 351-365. Derivation by mapping methods of collineation group in which variables are irrational invariants of quartic curve; system for group and associated canonical forms of quartic.

Differential Equations

On the Asymptotic Solution of the Non-Homogeneous Linear Differential Equation of the *n*th order. A Particular Solution, W. Van N. Garretson. Am. Jl. of Mathematics, vol. 40, no. 4, Oct. 1918, pp. 341-350. Considers non-homogeneous equation where roots of characteristic equation are distinct, and follow, at the outset, the method employed by Dini in his researches on linear differential equations published in Annali di Matematica, ser. 3, vol. 2 (1898), pp. 297-324 and vol. 3 (1899), pp. 125-183.

Fourier Theorem

Fourier's Theorem and the Trigonometric series (Sur le théorème de Fourier et les développements en series trogonométriques), G. A. Andrault. Revue Générale de l'Electricité, vol. 4, no. 10, Sept. 7, 1918, pp. 331-340, 3 figs. Method of demonstrating synthetically and generalizing Fourier's theorem and study of the physical significance and independence of the coefficients.

History of Mathematics

Plans for a History of Mathematics in the Nineteenth Century, Florian Cajori. Sci. vol. 48, no. 1238, Sept. 20, 1918, pp. 279-284, 2 figs. Determination of volume of mathematical literature to be penetrated. Before Am. Mathematical Soc.

Plane Algebraic Curves

On the Plane Algebraic Curves having Common Multiple Points (Sur les courbes algébriques planes ayant des points multiples communs), R. de Montessas de Ballore. Camptes Rendus des Séances de l'Académie de Sciences, vol. 167, no. 8, Aug. 19, 1918, pp. 290-293. Analytical investigation of contact of two curves of order *n*.

Pohlke's Theorem

Proof of Pohlke's Theorem and its Generalization by Affinity, Arnold Emch. Am. Jl. of Mathematics, vol. 40, no. 4, Oct. 1918, pp. 366-374, 3 figs. Proof of generalization and establishment of related propositions, by making use of affine collineations in space, of theorem: Three straight line segments of arbitrary length in a plane, drawn from a point and making arbitrary angles with each other, form a parallel projection of three equal segments drawn from the origin on three rectangular coördinate axes; however, only one of the segments, or one of the angles, can vanish.

Theta Modular Groups

Theta Modular Groups Determined by Point Sets, Arthur B. Coble. Am. Jl. of Mathematics, vol. 40, no. 4, Oct. 1918, pp. 317-340. Establishes theorems concerning connection between point set and theta modular function in discontinuous groups defined by $\vartheta_{a,k}$

MECHANICS

Arches

Direct Design of Curvature of Arches, Frank Barber. Can. Engr., vol. 35, no. 18, Oct. 31, 1918, pp. 379-381, 3 figs. Analytical method of finding ordinates of curve for concrete and masonry arches, with example.

Columns

Columns Subjected to Compression and Bending (Stänger, utsatta för tryck och böjning), A. Palmgvist. Teknisk Tidskrift, Väg och vatten Byggnadskonst, vol. 48, no. 9, 1918, pp. 137-142, 5 figs.

Motion, Dissipation of

The Law of Dissipation of Motion, Ernst Jonson. Am. Jl. of Sci., vol. 46, no. 274, Oct. 1918, pp. 578-580, 2 figs. Derivation of law by resolving motion resulting from collision of two particles into two perpendicular components in such a way that each component of one motion is parallel to one of components of other motion, and that the two components which have same direction have also same size.

Relativity, Principle of

The Principle of Relativity in Mechanics (Het relativiteitsbeginsel in de mechanica), G. J. Van de Well. De Ingenieur, year 33, no. 38, Sept. 21, 1918, pp. 736-747, 1 fig.

Shafts, Critical Velocity

A New Critical Velocity Occurring when the Bending of a Shaft is Accompanied by Vibrations (Eine neue kritische Wellengeschwindigkeit bei mit Biegung verbundenen Schwingungen), Gümbel. Dingler's polytechnisches Journal, vol. 333, no. 9, May 4, 1918, pp. 71-75, 2 figs.

A New Critical Velocity of Rotating Shafts (Eeine neue kritische Wellengeschwindigkeit), A. Stodola. Dingler's polytechnisches Journal, vol. 333, nos. 1 and 3, Jan. 12 and Feb. 9, 1918, pp. 1-3, 1 fig., and pp. 17-19. (From Schweiz. Bauzeitung, Nov. 1917). An important article on the critical velocity of shafts containing interesting new views.

Critical Speeds of Shafts, G. Bonner. Mech. World, vol. 64, no. 1654, Sept. 13, 1918, pp. 128-129, 1 fig. Diagrammatic representation of torsion, thrust and centrifugal action stresses. Before N. E. Section Junior Instn. of Engrs. (To be continued.)

Torsional Stresses

Torsional Stresses, F. W. Salmon. Machy., vol. 25, no. 2, Oct. 1918, pp. 108. Table for finding torsional stresses for various sizes of shafts and of various sections.

See also Aeronautics (Stresses in Structure); Cement and Concrete (Sections); Internal Combustion Engineering (Governors).

METAL ORES

Chromium

Chromite, J. C. Williams. Min. & Eng. Rec., vol. 23, nos. 15 and 16, Aug. 31, 1918, pp. 160-162. Foreign deposits, ore in United States; uses; alloys; description; occurrence; concentration; and recognition of this mineral.

Iron

The Occurrence of Iron Ores in East Netherlands (Het voorkomen van ijzeretsen in Oost Nederland), W. H. D. de Iongh. De Ingenieur, year 33, no. 34, Aug. 24, 1918, pp. 644-648, 2 figs.

Talc

Talc: Its Occurrences and Uses, Percy A. Wagner. Min. Mag., vol. 19, no. 4, Oct. 1918, pp. 218-220. Occurrences in South Africa and information as to uses throughout the world. From South African Jl. of Ind.

Tungsten

The Genesis of Tungsten Ores, R. H. Rastall. Min. Jl., vol. 123, no. 4338, Oct. 12, 1918, pp. 597-598. Sheelite deposits; secondary tungsten deposits. From Geological Mag. (Continuation of serial.)

METAL-WORKING TOOLS

Boring Machines

Cylinder Boring Machine. Can. Machy., vol. 20, No. 17, Oct. 24, 1918, p. 485, 1 fig. Although specially designed for boring cylinders of Liberty motors, the machine can, by slight changes in design of gearing, etc., be made to accommodate most boring operations.

Gidding and Lewis No. 4, Boring, Milling and Drilling Machine. Am. Mach., vol. 49, no. 17, Oct. 24, 1918, pp. 777-778, 1 fig. Principal dimensions and general description.

Centering Machine

Machine for Accurately Centering Shells. Can. Machy., vol. 22, no. 16, Oct. 17, 1918, p. 455, 1 fig. System followed by Modern Tool Mfg. Co.

Chisels

The Cold Chisel, J. A. Lucas. Coal Age, vol. 14, no. 16, Oct. 17, 1918, pp. 730-734, 27 figs. Various types of cold chisels and their uses.

Lathes

Massive Shell Lathes for Neville Island. Iron Age, vol. 102, no. 18, Oct. 31, 1918, pp. 1071-1074, 5 figs. Machine for boring and turning shells 12 in. in diameter and larger and features developed especially for operations in view.

Simplified Lathe Adapted to Shell Work. Iron Age, vol. 102, no. 16, Oct. 17, 1918, pp. 945-948, 13 figs. Description of 16- and 25-in. simplified Gisholt lathes.

Locomotive Repair Tools

Repairing Locomotive Fittings, Frank A. Stanley. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 663-665, 8 figs. Description of tools used in Californian railway repair shop.

METALLURGY

Brass

Thermal Expansion of Alpha and of Beta Brass between 0-600 Deg. Cent., P. D. Merica and L. W. Sehad. Jl. Franklin Inst., vol. 186, no. 4, Oct. 1918, p. 511. Comparison of thermal expansions of two constituents, alpha and beta, of which 60:40 brass is composed. (Abstract.)

Bronze, Phosphorus Content

Estimating Phosphorus in Bronzes, R. E. Rooney. Practical Engr., vol. 58, no. 1648, Sept. 26, 1918, p. 153. Table showing results obtained with different samples of commercial bronze by rapid and gravimetric methods of analysis.

Copper

Pure Carbon-Free Manganese and Manganese Copper, Arthur F. Braid. Bul. Am. Inst. Min. Engrs., no. 143, Nov. 1918, pp. 1697-1698. Deoxidizers and their uses in copper alloys.

Flue Gases

Precipitation from Flue Gases. Elec. Rev., vol. 73, no. 15, Oct. 12, 1918, p. 575, 2 figs. Description of installation at copper refinery where copper particles are recovered by the Cottrell process.

Grain Growth

Grain Growth in Metals, Zay Jeffries. Practical Engr., vol. 58, no. 1648, Sept. 26, 1918, pp. 151-153. Definition of germinative temperature; general laws of grain growth; typical examples. (Continuation of serial.)

Hardness of Metals

Hardness and Hardening, T. Turner. Metal Ind., vol. 16, no. 10, Oct. 1918, pp. 460-464, 1 fig. Address before British Inst. of Metals, Sept. 1918.

See also Engineering Materials (Copper), (Gun Metal).

MILITARY ENGINEERING

Ambulance Trains

An Ambulance Train for the American Army. Engineer, vol. 126, no. 3274, Oct. 27, 1918, pp. 260-262, 15 figs. Drawings and description of the British-built American ambulance train for American army.

Artillery

On the Propagation of Sound of a Cannon at a Great Distance (Sur la propagation du son du canon à grande distance), Maurice Collignon. Comptes Rendus des Séances de l'Académie des Sciences, vol. 167, no. 9, Aug. 26, 1918, pp. 333-335. Table of results of experimental work.

Variation of the Sight Position in Firing at Different Angles of Elevaton (Aenderung

der Visierstellung beim Schiessen unter vorschiedenen Geländewinkeln), K. Michalke. Dingler's polytechnisches Journal, vol. 333, no. 10, May 18, 1918, pp. 82-84, 5 figs.

Explosives

Digging Pole Holes with Dynamite, C. R. Van Drnff. Telephony, vol. 75, no. 18, Nov. 2, 1918, pp. 36-38, 4 figs. Method of blasting holes with dynamite to produce satisfactory results in different kinds of soil.

Sengite: The New South African Explosive, J. P. Udal. Min. Mag., vol. 19, no. 4, Oct. 1918, pp. 215-216. Gun-cotton base explosive, made by same process as tonite but substituting nitrate of soda for nitrate of barium. From South American Jl. of Ind.

Supply Base

Army Supply Base, South Brooklyn, N. Y. Contracting, vol. 7, no. 9, Nov. 1, 1918, p. 279. Placing of more than 11,000 yd. of floor and roof concrete.

See also Chemical Technology (Ammonia); Chemical Technology (Explosives); Safety Engineering (Explosives).

MINES AND MINING

Drills

Diamond-Drilling in Cornwall, J. A. MacVicar. Min. Mag., vol. 19, no. 4, Oct. 1918, pp. 184-187. Work done with Sullivan diamond-drill and author's opinion as to future possibilities.

Improved Sharpener Dies Make Better Drill Bits, Howard T. Walsh. Alaska & Northwest Min. Jl., vol. 12, no. 10, Oct. 1918, p. 91, 3 figs. Chart showing results obtained by one of largest copper mines in United States.

Efficiency

Increasing Coal Mine Efficiency, Charles E. Stuart. Coal Age, vol. 14, no. 16, Oct. 17, 1918, pp. 724-727, 5 figs. First of a series of articles on mine efficiency.

Engineers

The Work of the Mining Engineer, R. S. McCaffrey. Wisconsin Engr., vol. 22, no. 7, April 1918, pp. 285-286. Requirements of mining geology, mine engineering, and metallurgy.

Mine Gases

The Limits of Complete Inflammability of Mixtures of Mine Gases and of Industrial Gases with Air, Geo. A. Burrell and Alfred W. Ganger. Sci. Am. Supp., vol. 86, no. 2232, Oct. 12, 1918, p. 236, 2 figs. Results of experiments. From Tech. Paper 150, Bureau of Mines, Dept. of Interior.

Oil Shales

A Possible Fuel Oil Industry for Canada, James Ashworth. Can. Min. Jl., vol. 39, no. 19, Oct. 1, 1918, pp. 330-331. Discusses possibilities of encouraging production of oil and other by-products from coal and oil shales.

Ventilation

Canvas Tubing for Mine Ventilation, Lester D. Frink. S. A. Min. Jl., vol. 27, part 2, no. 1406, Sept. 7, 1918, p. 421. Explains manner in which canvas tubing is being used in the North Butte Co.'s mines at Butte, Mont. (To be continued.)

Water in Mines

The Unwatering of the Pensford Colliery, Charles Lewis. Iron & Coal Trades Rev., vol. 97, no. 2640, Oct. 4, 1918, pp. 371-374, 6 figs. Before South Wales Branch of Assn. of Min. Elec. Engrs., Sept., 1918.

See also Electrical Engineering (Induction Motors); Safety Engineering (Mine Rescue).

MOTOR-CAR ENGINEERING

Alcohol

The Utilization of Alcohol and Mixtures of Alcohol with Hydrocarbons, such as Benzole instead of Gasoline in Motor Cars, D. Tagneyeff (in Russian). Proc. of Russian Technical Soc., year 1917, nos. 4-7, Apr.-July, pp. 51-57, 1 fig. Data of work carried out by various German engineers.

Crane Tractor

An Electric Crane Tractor. Can. Machy., vol. 20, no. 14, Oct. 3, 1918, pp. 399-400, 1 fig. Machine with 15-ton trailing load capacity and provided with removable battery compartment.

Engines

Dorris Two-Ton Truck Model K-4. Automotive Ind., vol. 39, no. 12, Sept. 19, 1918, pp. 508-509, 4 figs. Detachable cylinder head doing away with valve cages.

Steam Motors

A New Coke Fuel Steam Motor. Engineer, vol. 126, no. 3266, Aug. 2, 1918, pp. 101-103, 11 figs. Details of coke fuel boiler and steam engine used in new steam automobile.

Tires

Tires for Tractor and Similar Vehicle Wheels. India-Rubber Jl., vol. 56, no. 14, Oct. 5, 1918, p. 6, 4 figs. Invention said to enable any existing tractor wheel of any diameter to be readily fitted with a number of studs or projections which will improve grip of wheel.

Tractors

The Wolverine Tractor. Auto, vol. 23, no. 40, Oct. 4, 1918, pp. 733-735, 7 figs. General features of 2-ton 30-50 hp. for three-furrow plowing.

Transmission

The Nuttall Traction Transmission. Automotive Ind., vol. 39, no. 12, Sept. 19, 1918, pp. 506-507, 4 figs. Designed to give two forward speeds and reverse and adaptable to either a longitudinally or a transversely mounted engine.

See also Hoisting and Conveying (Tractor-Trailer); Transportation; Electrical Engineering (Magneto), (Storage Batteries); Internal-Combustion Engineering; Roads and Pavements (Motorized Equipment).

MUNICIPAL

Poles

Joint Usage of Poles—A War Economy, T. N. Bradshaw. Elec. World, vol. 72, no. 18, Nov. 2, 1918, pp. 840-841, 1 fig. Statement of civic, economic and safety advantages resulting from adoption of practice; opinions regarding the form of construction which should be employed. Paper before International Assn. of Municipal Electricians, Atlanta, Sept. 1918, by A. L. Pierce.

Sanitary Survey

A Sanitary Survey of a City. Mun. Jl., vol. 45, no. 19, Nov. 9, 1918, pp. 359-361, 3 figs. Account of survey made by a State board of health. (To be concluded.)

Street Cleaning

A Report on Street Cleaning. Good Roads, vol. 16, no. 17, Oct. 26, 1918, pp. 160-161. Text of report submitted to Am. Soc. of Mun. Improvements by its committee on street cleaning.

Motor Apparatus in Buffalo Street Department, W. F. Schwartz. Mun. Jl., vol. 45, no. 17, Oct. 26, 1918, pp. 317-318, 1 fig. Sweepers and flushers. Before Am. Soc. Mun. Improvements.

Street Cleaning in San Francisco, Chas. W. Geiger. Mun Jl., vol. 45, no. 17, Oct. 26, 1918, pp. 315-317, 7 figs. Downtown streets swept by day and flushed by night; districting and increasing efficiency of force.

Surveying

Problems in City Surveying, W. W. Perrie. Can. Engr., vol. 35, no. 12, Sept. 19, 1918, pp. 257-260, 3 figs. and (discussion), pp. 260-261, 1 fig. Classification and description of resurveys. Before Assn. of Ontario Land Surveyors.

See also Lighting (Street Lighting); Sanitary Engineering.

MUNITIONS

Ammonia

Why We Are Asked to Conserve Ammonia, W. F. Sutherland. Power House, vol. 11, no. 10, Oct. 1918, pp. 290-291. Importance of ammonia in modern warfare.

Chucks

Chuck for Three-Inch Shrapnel Shells, Donald A. Baker. Machy., vol. 25, no. 2, Oct. 1918, pp. 111, 3 figs. Decribes and gives drawings of chuck.

Explosives

Military Explosives of Today (III.), J. Young. Jl. Roy. Soc. of Arts, vol. 66, no. 3439, Oct. 18, 1918, pp. 733-742, 4 figs. Requirements and classification of high explosives for shell filling; methods of detonation; tests for explosives; rate of detonation.

Fuses

Making the Mark III Detonating Fuse, Edward K. Hammond. Machy., vol. 25, no. 2, Oct. 1918, pp. 137-144, 13 figs. (Second article.)

Guns

The Development of Gun Manufacture, W. H. W. Skerrett. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 655-661, 9 figs. Reviews construction and manufacture of guns from earliest times up to present high-pressure methods.

Shell Assembling Die

Shell Base-Cover Assembling Die and Press, P. H. White. Machy., vol. 25, no. 2, Oct. 1918, pp. 109, 5 figs. Describing a die and press developed by Root-Van Dervoort Engineering Co. of East Moline, Ill.

Shells

Cast-Iron Shells in Permanent Moulds, Edgar A. Custer. Foundry Trade Jl., vol. 20, no. 201, Sept. 1918, pp. 471-473, 2 figs. Essentials in their manufacture and data on a 1100-lb. casting.

High Explosive Shells and Shrapnel, J. M. Hall. Iron & Steel Inst. of Can., vol. 1, no. 8, Sept. 1918, pp. 333-338, 4 figs. Outline of general practice as used by one of largest producers. Before Steel Treating Research Soc.

Machining and Gaging 9.2-inch High-Explosive Howitzer Shells, M. H. Potter. Machy., vol. 25, no. 2, Oct. 1918, pp. 125-132, 17 figs. Machines and tools used, successive order of machining operations, and complete gaging equipment.

Making Semi-Steel Projectiles. Iron Age, vol. 102, no. 15, Oct. 10, 1918, pp. 879-883, 22 figs. Method of molding, including core making, and machining as practiced by American Radiator Co., at Buffalo.

The British 6-in. Howitzer, I. W. Chubb. Am. Mach., vol. 49, no. 16, Oct. 17, 1918, pp. 697-704, 24 figs. Breech mechanism. (Fourth article.)

Small Arms

Revolvers and Automatic Pistols (Les revolvers et les pistolets automatiques), L. Cabanes. Génie Civil, vol. 73, no. 6, Aug. 10, 1918, pp. 110-113, 12 figs. Mauser, 1912 model; parabellum; Manlicker, 1900. (Continuation of serial.)

Stokes Gun

The Stokes Bomb-Throwing Gun (II), Wilfred Stokes. Sci. Am. Supp., vol. 86, no. 2232, Oct. 12, 1918, pp. 228-230, 14 figs. Details of projectile and of propellant; range; time fuse; percussion fuse. (Concluded.) Also in Sci. Am. Supp., vol. 86, no. 2231, Oct. 5, 1918, pp. 212-213, 10 figs.

See also Metal-Working Tools (Lathes); Forging (Shell Forging); Testing and Measurements (Shell Steel).

PAINTS AND FINISHES

Oil, Infected

Paint Disease, James Scott. Ry. Engr., vol. 39, no. 465, Oct. 1918, pp. 198-199, 3 figs. Experimental confirmation of author's previous statement in regard to destructive effect of infected oil.

PHYSICS

Acoustics

Note on the Theory of the Double Resonator, Lord Rayleigh. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 213, Sept. 1918, pp. 231-234. Direct mathematical consideration of the general case of a double resonator where two reservoirs of different volumes communicate with each other and with the atmosphere by narrow passages. This case cannot be treated by formula given in author's Theory of Sound.

Adsorption of Gases

The Adsorption of Gases on Plane Surfaces of Glass, Mica and Platinum, Irving Langmuir. Jl. Am. Chem. Soc., vol. 40, no. 9, Sept. 1918, pp. 1361-1403. Experimental confirmation of author's theory of adsorption—that it is the result of time lag between condensation of gas molecule impinging on solid and its subsequent evaporation—against results obtained by other investigators who claim that adsorbed films are relatively thick.

Aggregation

A Geometrical Basis for Physical and Organic Phenomena, John Millis. Science, vol. 48, no. 1241, Oct. 11, 1918, pp. 353-360, 1 fig. Geometrical analysis of principle stated in previous paper by writer: In any aggregation of an indefinite number of equal spherical bodies an arrangement giving minimum total volume occupied and perfect symmetry is impossible.

Air

Physics of the Air, W. J. Humphreys. Jl. Franklin Inst., vol. 186, no. 4, Oct. 1918, pp. 481-510, 3 figs. Types and latitude variation of aurora polaris; gradient wind velocity tables for every 5 deg. of latitude from 25 to 60 deg. (Concluded.)

Arc, Circular

Some Two-Dimensional Potential Problems Connected with the Circular Arc, W. G. Bickley. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 213, Sept. 1918, pp. 273-279, 6 figs. Drawings of stream lines in case of disturbance due to infinitely long lamina in the form

of circular arc, examination of case of rotation of the arc, and brief discussion of motion of arc when free to move and acted upon by the consequent fluid pressures.

Arc, Electric, in Gases

Experimental Examination of the Arc in Gases under Pressure, W. Mathiesen. Elecn., vol. 81, no. 2106, Sept. 27, 1918, pp. 451-452, 2 figs. Abstract of article in Elektrotechnische Zeitschrift, no. 49, 1917.

Crystals

New Method of Analysis of Crystals by Means of X-Rays (Nouvelle méthode d'analyse des cristaux au moyen des rayons X). Revue Générale des Sciences, year 29, nos. 15-16, Aug. 15-30, 1918, pp. 449-450. Method consists of photographing diffraction image obtained by passing narrow pencil of monochromatic X rays through an ensemble of small crystals of substance.

Evaporation

The Evaporation of Small Spheres, Irving Langmuir. Phys. Rev., vol. 12, no. 5, Nov. 1918, pp. 368-370. Suggests theoretical explanation for phenomena observed in experiments on evaporation of small iodine spheres of about one millimeter diameter performed by Harry W. Morse and described in Proc. Amer. Acad. Arts & Sci., vol. 45, Apr. 1910.

Heat

Is the Principle of Equivalence a Consequence of Carnot's Principle? (Le principe de l'équivalence est-il une conséquence du principe deCarnot?), C. Raveau. Comptes Rendus des Séances de l'Académie des Sciences, vol. 167, no. 9, Aug. 26, 1918, pp. 329-331. On the nature of heat as directly deductible from the postulate of Carnot.

Optics

An Optical Method for Accurately Dividing a Circle into Degrees, R. S. Clay. Sci. Am. Supp., vol. 86, no. 2229, Sept. 21, 1918, pp. 188-189, 5 figs. Based on symmetrical images by two inclined mirrors. From Trans. Optical Soc., London.

The Scattering of Light by Air Molecules, R. W. Wood. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 213, Sept. 1918, pp. 272-273. Result of experiments indicating that ultra-violet light causes precipitation of something from air, causing a slight cloud.

State, Equation of

On the Influence of the Finite Volume of Molecules on the Equation of State, Megh Nad Shaha and Satyendra Nath Basu. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 212, Aug. 1918, pp. 199-202. Argument to show that b in van der Waal's equation of state, taking into account finiteness of molecules and influences of forces of cohesion, does not properly represent influence of finite molecular volumes.

Vibrations

Forced Vibrations Experimentally Illustrated, E. H. Barton and H. M. Browning. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 212, Aug. 1918, pp. 169-178, 2 figs. Types of experiments illustrating qualitatively and quantitatively the chief phenomena concerned with forced vibrations similar to the ones occurring in resonance tubes, fluorescence, Lodge's syntonic jars, Hertz's oscillator and resonator, and wireless telegraphy; detailed theory explaining them.

On Kirchhoff's Formulation of the Principle of Huygens, A. Anderson. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 213, Sept. 1918, pp. 261-270, 3 figs. Deviation in usual procedure to establish Kirchhoff's formula consisting in beginning with a single source and assuming that the vibrational velocity at a distance r from source of disturbance is $(M/r)\ \Phi\ (t - \frac{r}{a})$, where M is a constant and a the velocity of propagation.

PIPE

Joints

Cement Joints for Gas Mains. Eng. & Cement World, vol. 13, no. 4, Aug. 15, 1918, pp. 21-23, 3 figs. Suggestions regarding design of cement joints made from experimental tests conducted at Iowa State college, Ames, and Highland Park College, Des Moines. Abstract of article in Iowa Engr., Apr. 1918.

Sewer Pipe

How Glazed Cement Sewer Pipe Is Made. Cement & Eng News, vol. 30, no. 8, Aug. 1918, p. 22. Description of Process followed by a Cal. manufacturing concern.

Winter Breakages

Methods for Obviating Pipe Breakages in Winter (Beseitigung der Gefahr von Rohrbrüchen bei Frostwetter), Lorenz. Journal für Gasbeleuchtung, year 61, no. 20, May 18, 1918, pp. 236-237.

POWER GENERATION AND SELECTION

Agriculture

Note on the Applications of Electricity to Agriculture (sur les applications de l'électricité a l'agriculture). Revue Générale de l'Electricité, vol. 4, no. 10, Sept. 7, 1918, pp. 352-354. Conditions under which a central station for rural power consumption can be installed.

Costs

Mastering Power Production, Walter N. Polakov. Indus. Management, vol. 56, no. 4, Oct. 1918, pp. 321-329, 6 figs. Principle of essential cost and use of standard cost. (Ninth article.)

Docks

Utilization of Electricity in Docks and Harbors. Shipbuilding & Shipping Rec., vol. 12, no. 9, Aug. 29, 1918, pp. 205-206. Review of possibilities opened up by recommendations of Coal Conservation Committee recently issued by Ministry of Reconstruction.

Dredging

Using Electric Power to Dredge a Relocated River Channel, J. H. Walter. Eng. News-Rec., vol. 81, no. 16, Oct. 17, 1918, pp. 723-725. Washington Counties build suction dredge operated by 800-horsepower motor.

Isolated Plant

Interconnection Will Help Coal Situation. Power House, vol. 11, no. 10, Oct. 1918, pp. 294-296. Considerations on practicability of interconnecting isolated plants with central station.

Quarry

The New Modern Rock Crushing Plant of the Brownell Improvement Company. Cement Eng. News, vol. 36, no. 8, Aug. 1918, pp. 38-39, 1 fig. Quarry operations and details of power plant and electrical features.

Rolling Mills

Electrification of a Steam-Driven Three-High Merchant Mill at the Frodingham Iron and Steel Works. Elecn., vol. 81, no. 2098, Aug. 2, 1918, pp. 297-299, 4 figs. Account of some problems which were solved in making change from steam to electricity.

Statistics of Consumption

Power Consumption of National Industries, L. W. Schmidt. Power, vol. 48, no. 18, Oct. 29, 1918, pp. 628-630. An attempt by author to evolve a scheme according to which power requirements of leading national industries should be measured with a view to facilitating regional distribution and to prevent waste; a statistical table accompanies article.

Waste Heat

The Utilization of Waste Heat from Open-Hearth Furnaces for the Generation of Steam, Thomas B. Mackenzie. Iron & Steel Inst., advance copy, paper 12, Sept. 12-13, 1918, 24 pp., 4 figs. Report of tests conducted by author with acid-lined open-hearth furnace of 30 tons nominal capacity and Babcock and Wilcox water-tube boiler having 720 sq. ft. heating surface.

Water Power

Power Possibilities in California, F. H. Fowler. Jl. of Elec., vol. 41, no. 9, Nov. 1, 1918, pp. 393-395, 2 figs. Survey of streams indicating where maximum development has already been reached, drawbacks of certain localities and advantages of others.

The Energy Supply of North America, C. P. Steinmetz. Elec. News, vol. 27, no. 20, Oct. 15 1918, pp. 22-24 and 38. Urges conservation of coal and utilization of all possible water powers. Before Am. Inst. Elec. Engrs.

See also Air Machinery (Wind Power); Hydraulic Engineering (Inter-connected Plants).

POWER PLANTS

Argentine

Power Supply for the Central Argentine Electrification. Elec. Ry. Jl., vol. 52, no. 15, Oct. 12, 1918, pp. 646-650, 3 figs. Description of steam turbine electric power station supplying traction, lighting and power requirements in suburbs of Buenos Aires. Also in Elec. World, vol. 72, no. 15, Oct. 12, 1918, pp. 684-687, 3 figs.

Boiler-Room Management

See Operation.

Boiler Settings

Tight Boiler Settings an Aid to Economy, J. E. McCormack. Power House, vol. 11, no. 10, Oct. 1918, pp. 292-293. Instances under author's observation and suggestions to secure air-tightness.

Costs

Plant Arrangement and Costs of Construction. Elec. World, vol. 72, no. 17, Oct. 26, 1918, pp. 780-782, 4 figs. Features of latest station of Turners Falls Power & Electric Company, Chicopee Junction, Mass. (First article.)

Engine Economy

Increasing Engine Economy, M. A. Saller. Power Plant Eng., vol. 22, no. 21, Nov. 1, 1918, pp. 870-873, 7 figs. Effects on capacity and efficiency of running engine condensing. (Fourth article.)

Floods

The Power Station at Millers Ford. Elec. Rev., vol. 73, no. 16, Oct. 19, 1918, pp. 603-608, 7 figs. Description of features of new steam-electric power plant of Dayton Power Light Co. Precautions against floods.

Hydroelectric

Fourth Successive Hydro-Electric Plant Nears Completion at Rumford, Maine. Eng. News-Rec., vol. 81, no. 15, Oct. 10, 1918, pp. 654-657, 6 figs. Development, begun in 1892, has increased from 200 to 30,000 hp. Description with map and sketches of the new work.

Malamort Electric Power House (L'usine électrique de Malamort), A. Boudrau. Revue Générale de l'Electricité, year 29, nos. 15-16, Aug. 24, 1918, pp. 270-274, 6 figs. Account of development of hydroelectric power station.

New Hydroelectric Plant of Montana Power Company, W. A. Scott. Elec. Rev., vol. 73, no. 14, Oct. 5, 1918, pp. 535-537, 2 figs. (Second article.)

Instruments

See Operation.

Operation

Arrangements to Avoid Operating Difficulties. Elec. World, vol. 72, no. 16, Oct. 19, 1918, pp. 732-734, 8 figs. Description of a plant in Dayton, Ohio, in which special attention has been given to handling coal economically, obtaining clean intake water, providing flexible piping layout and furnishing adequate boiler-room instruments.

Boiler-Room Management Plan, T. N. Wynee. Elec. World, vol. 72, no. 12, Sept. 21, 1918, pp. 549-552, 5 figs. How fifty to one hundred thousand dollars is saved annually by Indianapolis Company in trained boiler-room men and in adequate boiler-room equipment. From paper before Indiana Electric Light Assn., Aug. 1918.

Power Plant Management; The Use of Instruments, Robert June. Power House, vol. 11, no. 10, Oct. 1918, pp. 281-283, 7 figs. Summary of best current practice.

The Millers Ford Station. Power Plant Eng., vol. 22, no. 20, Oct. 15, 1918, pp. 825-831, 10 figs. Unique method of handling condenser water, flood protection; electrical layout; description of steam-electric plant at Dayton, O.

Waterworks Operation. Mun. Jl., vol. 45, no. 17, Oct. 26, 1918, pp. 322-324. Using records for increasing efficiency; analyzing flue gases; soot blowers; steam jets; chain grate, overfeed and underfeed stokers.

Power Factor

Getting the Maximum Out of Equipment, Will Brown. Elec. World, vol. 72, no. 17, Oct. 26, 1918, pp. 791-793, 1 fig. The power producer and the user must coöperate in order to improve power factor, otherwise adequate power to meet essential needs may not be available in approaching winter; remedy readily applicable.

Power-Factor Correction, an Urgent Necessity, Will Brown. Elec. World, vol. 72, no. 18, Nov. 2, 1918, pp. 834-837, 1 fig. Overlapping of fall lighting and power loads together with fuel scarcity may curtail power unless power factor is improved; causes of low power factor, how to locate them and the proper remedies to apply.

Soot in Boiler Tubes

Keeping Boiler Tubes Free from Soot, W. Saller. Power House, vol. 11, no. 10, Oct. 1918, p. 297. Effect of soot accumulation on boiler efficiency.

Turbo-Electric

A New 25,000-kw. Power Plant for Dayton, Ohio. Power, vol. 48, no. 18, Oct. 29, 1918, pp. 620-624, 3 figs. Principal data and description of new turbo-electric plant.

Detailed Description of Recently Installed 45,000-kw. Turbine Generators, J. P. Rigsby. Elec. News, vol. 27, no. 20, Oct. 15, 1918, pp. 28-30. Westinghouse cross-compound, double-unit type, consisting of a high and low pressure turbine, each connected through a flexible coupling to its own generator, mounted on separate bedplates supported on foundations lying parallel to each other.

Water Softening

Use of Soda Ash in Water Softening, William Henry Hobbs. Ry. Rev., vol. 63, no. 18, Nov. 2, 1918, pp. 633-635. Emphasizes im-

portance of accuracy in adjusting treatment to individual needs.

See also Air Machinery (Air Supply to Boiler Room); Building and Construction (Wind Pressure), (Chimneys); Engineering Materials (Boiler Plates); Corrosion (Electrolytic Prevention).

POWER TRANSMISSION

Belting

Textile Belting for Driving and Conveying, A. Chadwick. India-Rubber Jl., vol. 56, no. 14, Oct. 5, 1918, pp. 1-5, 4 figs. Manufacture of sewn cotton ducks, balata, solid woven cotton, and solid woven hair belting. Before Lancashire Section of Textile Industry.

Magnetic Gearing

Magnetic Gearing Arrangement (fuelques dispositifs d'embrayage magnétique). Revue Générale de l'Electricité, vol. 4, no. 10, Sept. 7, 1918, pp. 354-356, 5 figs. Principle of operation and scheme of connections of an automatic differential type.

PRODUCER GAS AND GAS PRODUCERS

Wood Gasification

Some Data of Tests on Wood Gasification in Inclined Retorts in Sweden (Einige Mitteilungen über Versuche mit Holzvergasung in geneigten Retorten bei Värtagasverket in Stockholm, Schweden), Adolf Molin. Journal für Gasbeleuchtung, year 61, no. 5, Feb. 2, 1918, pp. 50-55, 5 figs.

PUMPS

Centrifugal

Progress in Water Works Pumping Machinery, L. D. Grisbaum. Fire & Water Eng., vol. 64, no. 12, Sept. 18, 1918, pp. 202-203. Development of centrifugal pumps and their various present uses.

Irrigation

Operating Features of a California Pumping Project. Elec. Rev., vol. 73, no. 14, Oct. 5, 1918, pp. 523-525, 4 figs. Terra Bella irrigation system operated entirely by motor-driven pumps supplied by central station.

See also Steam Engineering (Pumping Engines).

RAILROAD ENGINEERING, ELECTRIC

Electrification

Railway Electrification to Save Fuel, W. J. Davis. Jl. of Elec., vol. 41, no. 9, Nov. 1, 1918, pp. 411-412. Figures bringing out loss of fuel which results from present method of making each engine a power plant in itself.

Power House

Electrification of the Central Argentine Railway. Power, vol. 48, no. 16, Oct. 15, 1918, pp. 550-554, 5 figs. Details of power house and equipment.

Rolling Stock

Efficient and Systematic Maintenance Prolongs Life of Rolling Stock and Reduces Operating Costs. Elec. Ry. Jl., vol. 52, no. 14, Oct. 5, 1918, pp. 622-623, 5 figs. Account of methods of Evanston, Ill., Railway in cutting power costs and increasing fare collections.

Heavy Electric Traction on the Central Argentine. Elec. Ry. Jl., vol. 52, no. 14, Oct. 5, 1918, pp. 604-609, 7 figs. Details of rolling stock, power and brake control, collecting shoe and conducting rail.

Suburban Lines

Electric Railways in Argentina. Times Eng. Supp., no. 528, Oct. 1918, pp. 208-209, 3 figs. Details of transmission and distribution in Central Argentine suburban lines.

Track Switches, Automatic

Automatic Track Switches Release Men for Other Work, R. C. Cram. Elec. Ry. Jl., vol. 52, no. 16, Oct. 19, 1918, pp. 686-693, 18 figs. Study of development and present status of automatic and remote-control track switches with consideration of factors which have contributed to their evolution.

Universal Cars

The First Universal Car. Elec. Ry. Jl., vol. 52, no. 17, Oct. 26, 1918, pp. 729-730, 1 fig. Preliminary details of one-man, two-man pre-payment and post-payment car submitted by War Board to Housing Bureau.

See also Machine Shop (Gear Cutting).

RAILROAD ENGINEERING, STEAM

Alaska

Railroad Construction Progress in Alaska. Ry. Rev., vol. 63, nos. 14 and 15, Oct. 5 and 12, 1918, pp. 487-490, 7 figs and 537-539, 7 figs. Line between Seward and Anchorage completed; work on other sections well advanced.

Boilers

Constructing Locomotive Boilers and Fireboxes. Ry. Gaz., vol. 29, no. 12, Sept. 20, 1918, pp. 311-312, 2 figs. Operation of portable gap riveter.

Brazil

The Development of the Brazilian Railways. Ry. Age, vol. 65, no. 16, Oct. 18, 1918, pp. 701-704, 4 figs. Statistics of Brazilian railways; Brazil presented as important potential market for American railway supply manufacturers; statistics of imports of railway equipment.

Brakes

Importance of High-Speed Brakes in Railroad Operation (l'importance des freins rapides dans l'exploitation des chemins de fer), J. Cablier. Revue Générale de l'Electricité, vol. 4, no. 10, Sept. 7, 1918, pp. 351-352. Comparison of interest and amortization of involved expense with benefit derived in transportation service.

Cars

U. S. R. A. Standard Baggage Cars. Ry. Mech. Eng., vol. 92, no. 10, Oct. 1918, pp. 561-564, 6 figs. Description of 60-ft. and 70-ft. all steel baggage cars constructed for U. S. Railroad Administration.

Draft Gears

Draft Gears Should Be Maintained, L. T. Canfield. Ry. Mech. Eng., vol. 92, no. 10, Oct. 1918, pp. 565-567, 2 figs. Proper protection to car and to lading requires a system of periodical inspection and repairs.

Fireboxes

The Belpaire Firebox. Ry. Gaz., vol. 29, no. 12, Sept. 20, 1918, p. 308, 3 figs. Account of American experience with that type and subsequent design modifications required.

French Equipment

See Operation.

Heating, Train

The Coal Saving Problem and Train Heating. Ry. Gaz., vol. 29, no. 15, Oct. 11, 1918, pp. 383-384, 2 figs. Suggests apparatus for recovering waste heat. Before Instn. Locomotive Engrs.

Loading

Proper Methods of Loading Automobiles. Ry. Rev., vol. 63, no. 16, Oct. 19, 1918, pp. 565-569, 11 figs. Analysis of methods employed by shippers and a representative railroad.

Locomotive Crankpin

A Ball Bearing Crank Pin. Ry. Gaz., vol. 29, no. 15, Oct. 11, 1918, p. 385, 2 figs. Application of ball-bearing to crank pin of a 2-10-2 type. From Ry. Mech. Engr.

Locomotive Firing

The Economical Use of Coal in Railway Locomotives. University of Ill. Bul., vol. 16, no. 2, Sept. 9, 1918, 71 pp., 17 figs. Statement of facts concerning choice, distribution, storage, and use of coal, and suggestions intended to supplement efforts of railway men to save coal.

Locomotive Valve Gear

A New Locomotive Valve Gear. Ry. Gaz., vol. 29, no. 14, Oct. 4, 1918, p. 359, 1 fig. Motion of valve same as obtained with Stephenson gear, but eccentric motion work removed from between frames and applied to outside using double crank arm as substitute for eccentrics and straps.

Locomotives

First Standard 0-8-0 Switcher. Ry. Mech. Eng., vol. 92, no. 10, Oct. 1918, pp. 543-545, 5 figs. Description and principal data of standard switcher built for U. S. Railroad Administration. Also in Ry. Rev., vol. 63, no. 14, Oct. 5, 1918, pp. 513-515, 4 figs.

4-6-0 Passenger and Double Bogie Tender, London & South-Western Railway. Ry. Engr., vol. 39, no. 465, Oct. 1918, pp. 184-186, 2 figs. Dimensions of cylinders, wheels, valve gear, boiler, heating surface, and weights. Also in Ry. Gaz., vol. 29, no. 14, Oct. 4, 1918, p. 361, 1 fig.

4-6-2 Type Locomotive, Philadelphia & Reading Railway. Ry. Gaz., vol. 29, no. 15, Oct. 11, 1918, p. 387, 1 fig. Features and dimensions.

Heavy Mallet Compound for Virginian Railway. Ry. Rev., vols. 63 and 65, nos. 14 and 16, Oct. 5 and 18, 1918, pp. 497-498 and 688-691, 3 figs. General description with principal data.

Modern Locomotive Engine Design and Construction (XLII). Ry. Engr., vol. 39, no. 465, Oct. 1918, pp. 187-191, 4 figs. Effect of superheating on both steam and fuel consumption at various rates of expansion.

Pacific Type Locomotives for the Central of New Jersey. Ry. Age, vol. 65, no. 18, Nov. 1, 1918, pp. 769-770, 1 fig. Description and principal data.

U. S. R. A. Standard Six-Wheel Switching Locomotive. Ry. Age, vol. 65, no. 15, Oct. 11, 1918, pp. 655-657, 3 figs. Principal data, drawings and tonnage chart, with general description of smallest government engines.

Long Fork Railroad

The B. & O. Completes the Long Fork Railway, A. C. Clark. Ry. Age, vol. 65, no. 15, Oct. 11, 1918, pp. 663-665, 5 figs. Description of new line which is important step in development of coal resources of Kentucky.

Operation

Difficulties in Handling French Equipment, J. N. McVey. Ry. Rev., vol. 63, no. 16, Oct. 19, 1918, pp. 581-584. Trials encountered by Amer. Ry. Engrs. in handling foreign equipment.

Permanent Way

Stresses in Permanent Way. Ry. Engr., vol. 39, no. 465, Oct. 1918, pp. 191-194, 8 figs. Report of extensive tests made on two lines in United States, on various sections. (Continuation of serial.)

Rails

A Metallographic Investigation of Transverse-Fissure Rails with Special Reference to High-Phosphorus Streaks, G. F. Comstock. Bul. Am. Inst. Min. Engrs., no. 143, Nov. 1918, pp. 1699-1714, 17 figs. Experimental research of two proposed theories regarding formation of fissures: (1) that they are the result of fatigue of steel, and (2) that they are originated from a defect on steel.

Common Defects in Rail. Ry. Rev., vol. 63, no. 14, Oct. 5, 1918, pp. 498-501. From paper by C. W. Gennet before convention of Roadmasters & Maintenance of Way Assn., Chicago, Sept. 1918.

Relative Life of Manganese and Open-Hearth Rail on Curves, H. W. Roberts. Elec. Ry. Jl., vol. 52, no. 16, Oct. 19, 1918, pp. 697. Results of tests are given showing manganese rail to wear about seven times as long as open hearth.

Why Busy Rails Do Not Rust, Oliver P. Watts. Iron & Steel of Can., vol. 1, no. 9, Oct. 1918, pp. 359-361. Review of experimental investigations by various authors. Before Am. Elec. Chem. Soc.

Rates

Railway Rates, R. A. Lehfeldt. Jl. S. A. Instn. of Engrs., vol. 17, no. 2, Sept. 1918, pp. 19-26. Methods of economics as applied to engineering; comparison of American and South African units for passenger traffic.

Resistance

The Mechanics of Curved Resistance. Ry. Rev., vol. 63, no. 15, Oct. 12, 1918, pp. 527-531, 2 figs. A study, covering older theories with data of recent experiments. From paper by J. G. Sullivan contributed to Bulletin 207 of Am. Ry. Eng. Association. Also in Ry. Age, vol. 65, no. 15, Oct. 11, 1918, pp. 665-666.

Shops

Machining Locomotive Driving Boxes, Frank A. Stanley. Ry. Mech. Eng., vol. 92, no. 10, Oct. 1918, pp. 573-575, 11 figs. Outline of work as performed at the Sacramento shops of Southern Pacific.

New Devices in Soo Wheel Shop. Ry. Mech. Eng., vol. 92, no. 10, Oct. 1918, pp. 577-579, 5 figs. Shifting platforms at press and automatic discharging axle carrier add to efficiency of plant.

The Manufacture of Laminated Springs. Ry. Gaz., vol. 29, no. 15, Oct. 11, 1918, pp. 388-390, 4 figs. General layout of locomotive smithy and steam hammer shops.

Signaling

New Electric Interlocking at Clyde, Ill. Ry. Signal Engr., vol. 11, no. 10, Oct. 1918, pp. 306-307, 5 figs. Plant on Chicago, Burlington & Quincy for handling increased main line and yard movement due to heavier traffic.

Tenders

New Tender for Canadian Pacific Locomotives. Ry. Rev., vol. 63, no. 15, Oct. 12, 1918, pp. 525-526, 2 figs. Dimensioned drawing and general description.

Ties

Present Aspect of the Tie Situation. Ry. Rev., vol. 63, no. 14, Oct. 5, 1918, pp. 494-495. Principles governing buying and specification of cross ties and difficulties of correct price fixing. From remarks by John Foley at Annual Roadmasters' convention, Chicago, Sept. 1918.

Reinforced Concrete Ties on Southern Pacific. Ry. Rev., vol. 63, no. 16, Oct. 19, 1918, pp. 557-558, 4 figs. Practical solution of

problem faced in present-day shortage of wooden ties.

See also Metal Working Tools (Locomotive Repair Tools).

REFRACTORIES

Silica Bricks

The Manufacture of Silica Brick, H. Le Chatelier and B. Bogitch. Can. Min. Jl., vol. 39, no. 18, Sept. 15, 1918, pp. 314-317. Causes of failure of furnace roofs; why silica brick retains rigidity at high temperature; manufacturing operations. Paper before Am. Inst. of Min. Engineers, Milwaukee.

Tests

The Standardization of Tests for Refractory Materials, Cosmo Johns. Iron & Steel Inst., advance copy, paper 11, Sept. 12-13, 1918, 32 pp., 3 figs. Analysis of fire clays, raw ganisters, quartose, rocks, and manufactured products; analysis of dolomite and magnesite identification of the various forms of silica in silica bricks; porosity, water absorption and specific gravity tests; shrinkage of clays on drying and firing; tensile strength of dried clays; refractoriness and crushing strength. Prepared provisionally by a committee of refractories section of Ceramic Society.

REFRIGERATION

Refrigerating Plant, A. E. F.

Refrigerating Plant, Intermediate Depot for American Army in France, Robert K. Tomlin, Jr. Power, vol. 48, no. 17, Oct. 22, 1918, pp. 596-598, 4 figs. Description of plant to care for 5000 tons of meat.

Throttling of Ammonia

Throttling of Ammonia, Charles H. Herter. Power, vol. 48, no. 15, Oct. 15, 1918, pp. 530-531. Discusses question of whether it is better to regulate several expansion valves singly, or main liquid valve at receiver.

RESEARCH

British Committee

Scientific and Industrial Research. Third Annual Report. Iron & Coal Trades Rev., vol. 97, no. 2636, Sept. 6, 1918, pp 257. Report of Committee of Privy Council for Scientific and Industrial Research.

British National Physical Laboratory

Research the Mainstay of a Nation's Industries, Richard T. Glazebrook. Can. Machy., vol. 22, no. 16, Oct. 17, 1918, pp. 449-454, 5 figs. Work accomplished by Nat. Research Lab. of England.

The British National Physical Laboratory. Sci., vol. 48, no. 1238, Sept. 20, 1918, pp. 284-287. Brief report of work done during past year in electricity, heat, meteorology, aerodynamics and special research and investigations.

Cotton Manufacturers' Committee

Committee on Industrial Research. Textile World Jl., vol. 54, no. 19, Nov. 9, 1918, pp. 117-119. Report of committee of Nat. Assn. of Cotton Mfrs. on possibilities of research along lines connected with cotton manufacturing industry and best methods to carry it out.

See also Aeronautics (Research).

ROADS AND PAVEMENTS

Asphalt

Maintaining Old Asphalt Pavements in Buffalo, C. E. P. Babcock and J. A. Vandewater. Can. Engr., vol. 35, no. 15, Oct. 10, 1918, pp. 325 and 331-332, 2 figs. Average costs of repairs per yard at different ages to date of condemnation. Before Am. Soc. Mun. Improvements.

Cracks

The Prevention of Longitudinal Cracks in Hard-Surfaced Pavements, Wm. C. Perkins. Good Roads, vol 16, no. 17, Oct. 26, 1918, pp. 158 and 161. Description of patented method of constructing foundations for brick, concrete and other surfacing. Before Am. Soc. Mun. Improvements.

Drainage

Drainage The Most Important Consideration Entering into Road Construction, J. H. MacDonald. Can Engr., vol. 35, no. 15, Oct. 10, 1918, pp. 327-329 and (discussion) pp. 329-331. Salient features of this question from local investigations. Before Fifth Annual Congress Can. Good Roads Assn.

The Maintenance of Drainage, R. A. Meeker. Good Roads, vol. 16, no. 12, Sept. 21, 1918, pp. 107-108, 2 figs. Its importance in care of roadway.

Fillers

The Choice of Fillers for Block Pavements. John S. Crandell. Mun. & County Eng., vol. 55, no. 4, Oct. 1918, pp. 127-130, 5 figs. Types of fillers; functions of a filler; granite block pavement.

Macadam

American Road Building in French War Zone Organized, Robert K. Tomlin. Highway Mag., vol. 9, no. 6, July 1918, pp. 1-3 and 6, 1 fig. Development of methods of constructing water-bound macadam from inspection by United States highway engineers of British and French Systems.

Maintenance Work

How Well-Maintained Roads are Secured, D. H. Winslow and Charles R. Thomas. Am. City, vol. 19, no. 4, Oct. 1918, pp. 266-270, 4 figs. Study of comparative benefits of local and central government in developing good roads, with special reference to North Carolina system of road maintenance.

Organization for Road Maintenance, L. H. Neilsen. Good Roads, vol. 16, no. 17, Oct. 26, 1916, pp. 157-158. Discussion of administration and operation of maintenance work in Michigan, with special reference to patrol system in township. Before Mich. State Good Roads Assn.

Motorized Equipment

The Motor Truck and Trailer in Road and Street Building, Repair and Maintenance. Cement Eng. News, vol. 30, no. 8, Aug. 1918, pp. 24-28. Data taken from records in office of a county engineer.

Repairs

War Time Road Repairs. Am. City, vol. 19, no. 4, Oct. 1918, pp. 259-261, 2 figs. Necessity of repairing roads and manner of keeping an earth road in satisfactory condition.

Rural Roads

Road Construction in Alberta, J. D. Robertson. Can. Engr., vol. 35, no. 13, Sept. 26, 1918, pp. 285-286. Experience in province with rural roads of sand, gravel, etc. Before Eng. Inst. of Can.

Slag

Roads During and After the War, E. Purnell Hooley. Can. Engr., vol. 35, no. 12, Sept. 19, 1918, pp. 265-266. Use of furnace slag as surface course. Before Instn. Mun. & County Engrs.

See also Cement and Concrete (Paving); Accounting (Highways).

SAFETY ENGINEERING

Accidents

Accident Prevention and Safety, a list of new books and articles received in the library of the National Workmen's Compensation Service Bureau, New York, September, 1918, 9 pp.

Foundation for the Assumption that 18 per cent of Industrial Accidents are Due to Defects in Lighting Installation, R. E. Simpson. Am. Gas Eng. Jl., vol. 109, no. 16, Oct. 19, 1918, pp. 364-366. Based on Travelers Insurance Co. records.

Works Accidents, Their Causes and Remedies. Can. Foundryman, vol. 9, no. 8, Aug. 1918, p. 175. Brief account of investigation conducted on behalf of the Health of Munition Workers' Committee.

Construction Work

Precautions for Reducing Accidents on Construction Work, W. J. Lynch. Can. Engr., vol. 35, no. 18, Oct. 31, 1918, p. 398. Before Construction Section of Nat. Safety Congress.

Dangerous Tools

Dangerous Tools and Appliances, Chesla C. Sherlock. Am. Mach., vol. 49, no. 16, Oct. 17, 1918, pp. 705-707. Review of some court findings on liability of employers.

Explosives

Handling and Storing Explosives, Arthur La Motte. Eng. & Min. Jl., vol. 106, no. 11, Sept. 14, 1918, pp. 488-493. (Nat. Safety Council.)

Fire Protection

Fire Protection of Turbo-Alternators (Protection contre les incendies de turbo-alternateurs), L. Conge. Revue Générale de l'Electricité, vol. 4, no. 10, Aug. 31, 1918, p. 322, 3 figs. Details of method permitting fire extinction by steam jet under pressure.

How Some Important Ship Fires were Fought, with Notes on Tools for Marine Fire-Fighting, Edward J. Worth. Quarterly of Nat. Fire Prevention Assn., vol. 12, no. 2, Oct. 1918, pp. 143-149. Before International Assn. of Fire Engrs.

Maintenance of Sprinkler Equipments during Cold Weather in Western Canada, John Young. Quarterly of Nat. Fire Protection Assn., vol. 12, no. 2, Oct. 1918, pp. 157-159. Practice in layout of water mains and of heating gravity tanks.

Oil Interrupters and Fire Protection (les interrupteurs à huile et la protection contre l'incendie), P. Torche. Revue Générale de l'Electricité, vol. 4, nos. 9 and 10, Aug. 31 and Sept. 7, 1918, pp. 311-319, 4 figs. and pp. 343-348, 2 figs. Aug. 31: Résumé of tests on interrupters undertaken by the Association Suisse des Electriciens for the purpose of establishing rules for construction use and installation of these apparatus. Sept. 7: Causes of explosion and analysis of American piston type, which, in author's opinion, is the only one safe against internal pressure.

Shipyard Fire Protection. Quarterly of Nat. Fire Protection Assn., vol. 12, no. 2, Oct. 1918, pp. 126-128. Notes on the organization of the Plant Protection Section of the Am. Fleet Corporation.

The Fire Risk on Vessels, Samuel D. McComb. Quarterly of Nat. Fire Protection Assn., vol. 12, no. 2, Oct. 1918, pp. 133-142, 2 figs. Study of hazards of marine transportation. From the Weekly Underwriter.

Grinding Wheels

Bursting Grinding Wheels, Chesla C. Sherlock. Am. Mach., vol. 49, no. 17, Oct. 24, 1918, pp. 767-769. Decisions of courts under various circumstances.

Health Conditions

Health of English Workmen in Munition Factories (la santé des travailleurs anglais dans les usines de munitions.) Revue Générale de l'Electricité, year 29, nos. 15-16, Aug. 15-30, 1918, pp. 451-452. Brief account of report of special committee appointed by British Government to study health conditions in industries.

Mine Rescue

Mine Rescue Apparatus. Engineer, vol. 126, no. 3272, Sept. 13, 1918, pp. 219-220, 4 figs. Report of a committee appointed to investigate types of breathing apparatus used in coal mines.

Punch Presses

Safe Punch Press Operation, W. W. Roach. Iron Age, vol. 102, no. 18, Oct. 31, 1918, pp. 1076-1077. Elimination of cuts and lacerations; mechanical guards; lighting and arrangement of machinery; safe practices. Paper before National Safety Council, St. Louis, Sept. 1918.

Spontaneous Heating

Spontaneous Heating of Grain and other Foodstuffs (Ueber die Selbsterhitzung von Getreiden und anderen Nährstoffen), J. F. Hoffman. Dinglers polytechnisches Journal, vol. 333, no. 8, Apr. 20, 1918, pp. 63-67, 1 fig.

Water Mains

Leakage from High-Pressure Mains and its Variation with the Pressure. Can. Engr., vol. 35, no. 13, Sept. 26, 1918, pp. 286-287, 1 fig. Report of service in fire system of Borough of Manhattan. From Jl. Am. Waterworks Assn.

Protection of Water Mains, Fire Hydrants and Valves in Winnipeg, Thomas H. Hooper. Quarterly of Nat. Fire Protection Assn., vol. 12, no. 2, Oct. 1918, pp. 159-160.

See also Hoisting and Conveying (Cranes); Mines and Mining (Mine Gases).

SANITARY ENGINEERING

Disinfection

Disinfection by Heat. Times Eng. Supp., no. 528, Oct. 1918, p. 207. Type of disinfectors; suggestions on conditions to be observed.

Drainage

Main Drainage and its Relation to River and Harbor Front Improvement, Morris Knowles and J. M. Rice. Can. Engr., vol. 35, no. 14, Oct. 3, 1918, pp. 297-302 and 318. Résumé of methods adopted in many of world's leading cities with detailed notes regarding design of Essex border intercepter. Before Am. Soc. of Mun. Improvements.

Plumbing

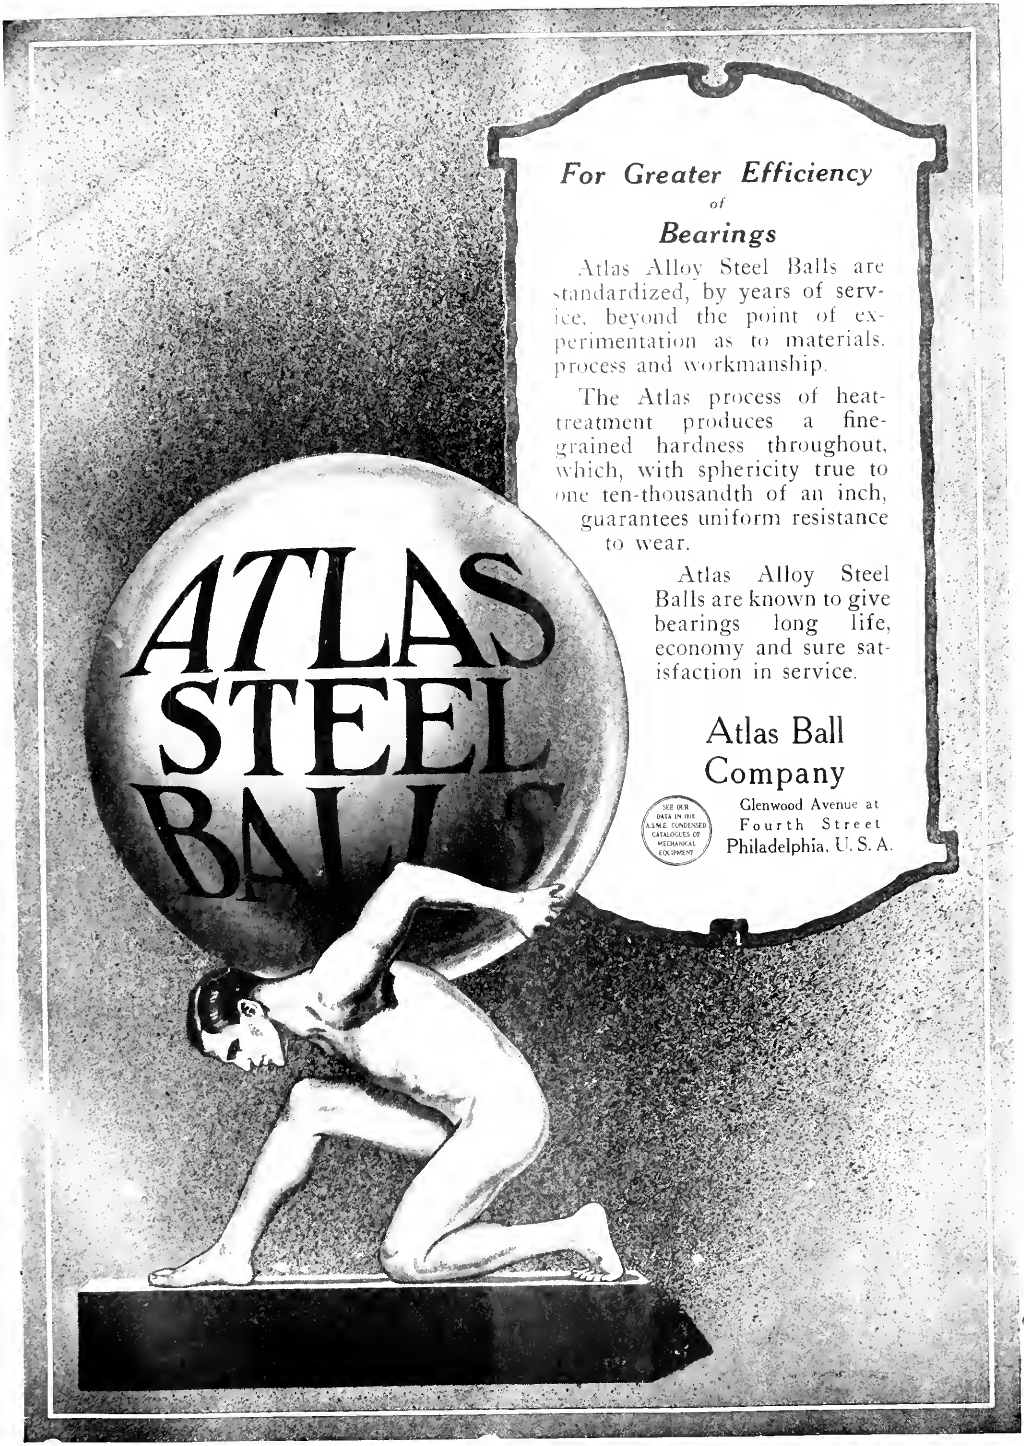
The Why and Wherefore of Sanitary Engineering, Arthur Bateman. Domestic Eng., vol. 35, no. 1, Oct. 5, 1918, pp. 5-7 and 32, 4 figs. Series on technical and scientific plumbing and sanitation.

Refuse Disposal

Refuse Incinerating Plants and their Operation, H. J. Harder. Mun. Jl., vol. 45, no. 17, Oct. 26, 1918, pp. 318-320. Tables giving name of city, capacity and other details of plant, and total cost per day.

Sanitation of Grounds

The Sanitation of Rural Workmen's Areas. Am. City, vol. 19, no. 4, Oct. 1918, pp. 275-278, 2 figs. Shows how to insure suitable living conditions for war-time industrial workers. From report of United States Public Health Service.



For Greater Efficiency
of
Bearings
Atlas Alloy Steel Balls are standardized, by years of service, beyond the point of experimentation as to materials, process and workmanship.
The Atlas process of heat-treatment produces a fine-grained hardness throughout, which, with sphericity true to one ten-thousandth of an inch, guarantees uniform resistance to wear.
Atlas Alloy Steel Balls are known to give bearings long life, economy and sure satisfaction in service.
Atlas Ball Company
Glenwood Avenue at Fourth Street
Philadelphia, U. S. A.

STEEL

Sewage

Catch Basin Cleaning. Can. Engr., vol. 35, no. 13, Sept. 26, 1918, pp. 287-288. Annual report of superintendent of Bureau of Sewers, Chicago.

First Unit of Improved Means of Sewage Disposal for Philadelphia Well Started, W. L. Stevenson. Eng. News-Rec., vol. 81, no. 14, Oct. 3, 1918, pp. 629-633, 3 figs. Design features include intercepting sewer partly under pressure, ventilated grit chamber with sand removing and washing plant, and depressed Venturi meter.

Main Sewage Treatment Plant of Rochester, F. A. Fisher and N. A. Brown. Mun. Jl., vol. 45, no. 17, Oct. 26, 1918, pp. 326-329. Description and operating data of detritus tanks, Riensch-Wurl screens, Imhoff tanks, sludge beds and power plant. Before Am. Soc. Mun. Improvements.

Miles Acid Treatment of Sewage. Mun. Jl., vol. 45, no. 17, Oct. 26, 1918, pp. 321-322. Conclusion of report upon experiment with this process.

Operating Sewage Plants. Mun. Jl., vol. 45, no. 17, Oct. 26, 1918, pp. 327-328. Abstract of instructions issued by Texas State Board of Health; tanks, sludge beds, filters, activated sludge; operation records.

Sewage Purification by Activated Sludge Process, W. R. Copeland. Can. Engr., vol. 35, no. 14, Oct. 3, 1918, pp. 302 and 315-316. Comparative degrees of purification obtained with different quantities of air.

Sewer Design and Construction. Mun. & County Eng., vol. 55, no. 4, Oct. 1918, pp. 130-132, 1 fig. Sewage collection and disposal proposed at Los Angeles harbor; conditions calling for separate or combined sewers.

The Private Sewerage Question, D. H. Wyatt. Can. Engr., vol. 35, no. 14, Oct. 3, 1918, pp. 310-311. Results produced by leaky building drains and building sewers.

Uses and Accomplishments of Chlorine Compounds in Water and Sewage Purification, C. A. Jennings. Am. City, vol. 19, no. 4, Oct. 1918, pp. 296-304, 3 figs. Remarks on comparative value of liquid chlorine and hypochlorite for disinfection of water and sewage.

Water Purification and Sewage Treatment. Mun. & County Eng., vol. 55, no. 4, Oct. 1918, pp. 138-143, 8 figs. Prevention of Imhoff tank foaming at Schenectady; design and construction features of the slow sand water filtration plant at Auburn; chlorination and filtration.

Water Pollution

Salinification of Rivers and Elimination of Waste Liquids from Soda Works (Die Versalzung der Flüsse und die Beseitignng der Kaliabwässer). Journal fur Gasbeleuchtung, year 61, no. 19, May 11, 1918, pp. 221-224.

Pollution of Boundary Waters, F. A. Dallyn. Can. Engr., vol. 35, no. 15, Oct. 10, 1918, pp. 323-325. Examination of final report of International Joint Commission. Before Am. Soc. Mun. Improvements.

STANDARDS AND STANDARDIZATION

Aircraft Materials

British Engineering Standards Association. Aeronautics, vol. 15, no. 255, Sept. 4, 1918, pp. 224-226. Report regarding standardization of aircraft materials and parts.

Gearing

Standardization of Gearing, B. F. Waterman. Mech. World, vol. 64, no. 1645, July 12, 1918, pp. 14-15. Outline of details which author thinks may be standardized in each type. (Am. Gear. Mfrs. Assn. Convention.)

Lamp Voltages

The Standardization of Lamp Voltages, Leon Gaster. Illuminating Engr., vol. 11, no. 7, July 1918, p. 170. Announcement of Tungsten Lamp. Assn. proposing simplification in that respect.

See also Marine Engineering (Standardized Ships.)

STEAM ENGINEERING

Boiler Furnace Walls

New Data on Boiler Walls, J. C. Taylor. Nat. Engr., vol. 22, no. 9, Sept. 1918, pp. 408-409. Dominant factors in erection and operation of boiler furnace walls.

Boilers

Boiler Room Efficiency, A. H. Blackburn. Publicity Mag., vol. 17, no. 5, Sept. 1918, pp. 7 and 12-13. Suggestions for intensive fuel economy. Paper before Smoke Prevention Assn.

Development of Steam Boiler Baffles, Albert A. Straub. Power, vol. 48, no. 19, Nov. 5, 1918, pp. 656-659, 9 figs. Examples of baffles developed to obtain maximum economy and capacity consistent with the primary features for which the baffle was designed.

Feeding and Circulating the Water in Steam Boilers, John Watson. Page's Eng. Weekly, vol. 33, no. 735, Oct. 11, 1918, pp. 172-174. Survey of devices developed in recent years. Before Inst. Marine Engrs.

Removing Tubes, Headers and Baffles in Water-Tube Boilers. Power, vol. 48, no. 17, Oct. 22, 1918, pp. 584-590, 12 figs. Detailed directions with illustrations telling how to take out tubes of water-tube boilers, how to put them in, how to go about removing and replacing cast-iron and wrought-iron tube headers and what must be done to put in new brick for the baffling in the tubes.

Condensers

Keeping Condenser Performance up to the Mark, Hartley Le H. Smith. Elec. Ry. Jl., vol. 52, no. 16, Oct. 19, 1918, pp. 694-697, 4 figs. How station engineer can determine economy he should obtain and how he can correct causes of low vacuum.

Economizers

Economizers from the Viewpoint of a Designing and Operating Engineer, Louis R. Lee. Power, vol. 48, no. 18, Oct. 29, 1918, pp. 637-638, 1 fig.

Wear and Tear of Fuel Economizers, Edward Ingham. Colliery Guardian, vol. 96, no. 3014, Oct. 4, 1918, pp. 707. External corrosion; internal corrosion; water hammer; overheating; flue gas explosions; importance of frequent examinations.

Exhaust Steam

Using Exhaust Steam, S. E. Balcome. Power Plant Eng., vol. 22, no. 20, Oct. 15, 1918, pp. 832-835, 3 figs. Value of exhaust steam; limitations of its use; effects of engine efficiency; heat available with various types of engines.

Pumping Engines

Pumping Engines for the Cairo Main Drainage. Engineering, vol. 106, no. 2749, Sept. 6, 1918, pp. 251-252, 9 figs. Drawings of details and general description of quadruple expansion engines.

Turbines

Steam Turbine Development and Tendencies. Elec. Rev., vol. 73, no. 16, Oct. 10, 1918, pp. 612-614, 3 figs. Rapid development of turbine in past giving place to gradual developments affecting economy, reliability, safety and increased capacity.

Steam Turbines for Natural Steam Power Plant at Larderello, Italy. Engineering, vol. 106, no. 2752, Sept. 27, 1918, pp. 339, 14 figs. General description with drawings and illustrations.

See also Motor-Car Engineering (Steam Motors); Power Plants (Turbo-electric).

STEEL AND IRON

Acid-Resisting Irons

Acid Resisting Irons. Can. Foundryman, vol. 9, no. 8, Aug. 1918, p. 178. Properties and uses of silicon alloys; typical analysis of duriron and tantiron. (See also Tantiron.)

Cast Iron

A Method for the Prevention of Growth in Grey Cast Iron, J. E. Hurst. Iron & Steel Inst., advance copy, paper 10, Sept. 12-13, 1918, 5 pp., 3 figs. Investigation of possibility of removing graphite without subsequent production of cavities in metal by superficial decarbonization, oxidation of graphite being followed by liquidation of phosphate eutectic with remaining cavities. Also in Iron & Coal Trades Rev., vol. 97, no. 2638, Sept. 20, 1918, p. 323. Paper before Iron & Steel Inst., Sept. 1918.

Avoiding Shrinkage Troubles in Cast Iron. Can. Foundryman, vol. 11, no. 9, Oct. 1918, p. 264. Suggestions of some foundrymen regarding use of riser on top of casting to provide sufficient metal to prevent shrinking.

Influence of Some Special Constituents on Cast Iron, A. Campion. Foundry Trade Jl., vol. 20, no. 201, Sept. 1918, pp. 467-470. Nickel, chromium, molybdenum, tungsten, boron, and vanadium.

Duriron

See Acid Resisting Irons.

Electric Steel

Electric Pig Iron from Steel Scrap, Robert Turnbull. Iron Age, vol. 102, no. 17, Oct. 24, 1918, pp. 1026-1027. Paper before Am. Electrochemical Soc., Atlantic City, Oct. 1918.

Electric Steel Making, Arthur V. Farr. Am. Mach., vol. 49, no. 17, Oct. 24, 1918, pp. 753-755, 4 figs. Describing process of making steel electrically and giving analysis of charge at various stages of process and at end of melt. Paper before Am. Drop Forge Assn., Buffalo, N. Y., June 1918.

The Electric Furnace in the Steel Cast Industry, W. E. Moore. Elec. Jl., vol. 15, no. 9, Sept. 1918, pp. 331-332. Comparative value of crucible melting, open hearth melting, side-blow converter and electric furnace in producing steel.

Hot-Deformation

Influence of Hot-Deformation on the Quantities of Steel, Georges Charpy. Iron & Steel Inst., Sept. 12-13, 1918, advance copy, paper 4, 19 pp., 10 figs. Tensile tests, shock bend tests and notch tests on blooms resulting from three gun metal equal ingots, made in acid furnace and reduced from common original section of 355 x 355 mm., the first to 225 x 225 mm, the second to 165 x 165 mm, and the third to 125 x 125 mm.

Ingots

The Cooling of Steel in Ingot and Other Forms, J. E. Fletcher. Iron & Steel Inst., advance copy, paper 5, Sept. 12-13, 1918, 40 pp., 20 figs. Experimental investigation of laws governing freezing and cooling of steel in metal and sand molds involving the determination of variable speed of cooling, measurements of temperature gredients and contraction, and observations on influence of cooling on crystalline structure. Also in Engineering, vol. 106, no. 2752, Sept. 27, 1918, pp. 342-344, 6 figs.; Iron & Coal Trades Rev., vol. 97, no. 2638, Sept. 20, 1918, pp. 315-318, 9 figs. Abstract of paper before Iron & Steel Inst., Sept. 1918.

Iron Metallurgy

Some Experiments on the Reaction between Pure Carbon Monoxide and Pure Electrolytic Iron below the A 1 Inversion, H. C. H. Carpenter and C. Coldron Smith. Iron & Steel Inst., Sept. 12-13, 1918, advance conv, paper 3, 53 pp., 39 figs. Investigation under two different sets of conditions: (1) those in which gaseous products were removed continuously by passing a stream of carbon monoxide over the iron, and (2) tobe in which they were allowed to accumudate in apparatus.

Malleable Iron

Phosphorus in Malleable Cast Iron, J. H. Teng. Iron & Steel Inst., advance copy, paper 16, Sept. 12-13, 1918, 19 pp., 13 figs. Experiments at University of Birmingham on two series of test-bars: (1) by adding phosphoric iron to a very pure American washed white iron, (2) by adding the same to iron supplied by Birmingham malleable iron founders.

The Addition of Steel to Cast Iron, J. E. Hurst. Sci. Am. Supp., vol. 86, no. 2232, Oct. 12, 1918, p. 235. Experiments illustrating absorption of carbon by steel during melting in cupola; results obtained on melting steel borings and crop ends from smithy in a cupola together with 10 per cent ferro silicon. Also in Engineer, vol. 126, no. 3266, Aug. 2, 1918, p. 93.

Open-Hearth Furnace

The Principles of Open-Hearth Furnace Design, Chas. H. F. Bagley. Iron & Steel Inst., Sept. 12-13, 1918, advance copy, paper 1, 19 pp., 5 figs. Discussion from scientific and practical points of view in the light of author's 15 years' experience in England, Germany and United States. Also in Iron & Coal Trades Rev., vol. 97, no. 2637, Sept. 13, 1918, 5 figs.

Pyrometry

Pyrometry Applied to the Hardening of High Speed Steels, J. O. Arnold. Trans. Faraday Soc., vol. 13, part 3, June 1918, pp. 271-275. Results obtained at Sheffield University using an average temperature of 1300 deg. cent.

Quenching

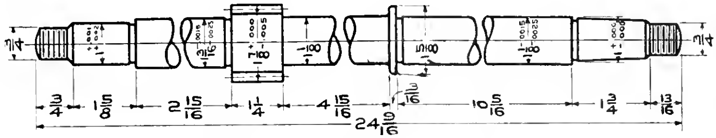
Note on the Warping of Steel through Repeated Quenching, J. H. Whiteley. Iron & Steel Inst., advance copy, paper 17, Sept. 12-13, 1918, 4 pp., 7 figs. Photographs showing change of shape of a cylindrical piece, weighing several pounds, which has been used for four years for warming small tank after being heated to blood-red heat. Also in Engineering, vol. 106, no. 2752, Sept. 27, 1918, pp. 340-341, 7 figs.

Spectra

A Comparative Study of the Flame and Furnace Spectra of Iron, G. A. Hemsalech. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 213, Sept. 1918, pp. 209-230, 7 figs. Experimental research leading autnor to conclude that iron spectra given by an electric-tube resistance furnace at atmospheric pressure and up to 2400 deg. cent. are caused by action of heat on a chemical compound of the metal and not on the free metal itself, that flame and furnace spectra are identical up to 2400 deg. cent., that the character of spectrum is independent of the nature of iron compound, and other similar results.

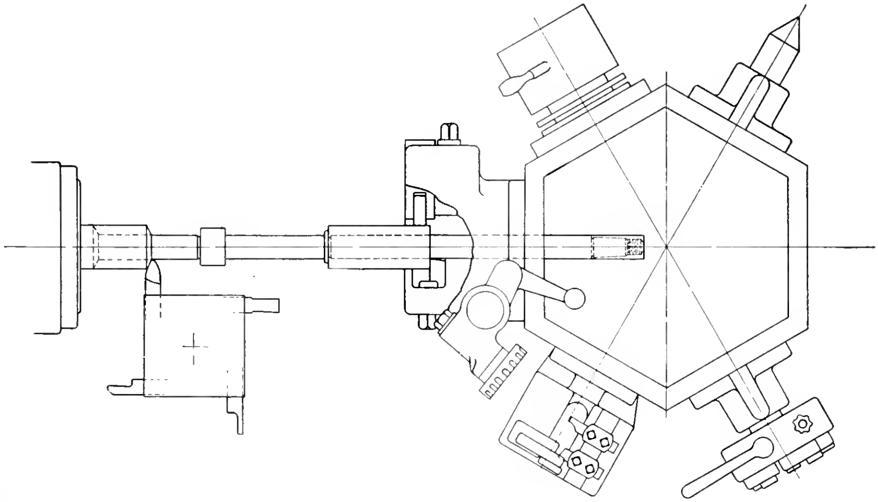
Steel

Composition and Properties of Steels, Howard Ensaw. Am. Mach., vol. 49, no. 15, Oct. 10, 1918, pp. 669-672, 1 fig. Composition of steels used for manufacture of various parts of intricate special machinery, especially airplane engines, requiring materials possessing



Follow This Thru

YOU will spend your time profitably by analyzing each operation in producing this shaft on the No. 2-A Universal Hollow Hexagon Turret Lathe.



1st Operation:—Turn the 1⅛ in. diameter with the turning tool. At the same time, with a cutter in the square turret, form the 1⅝ in. shoulder and turn the 1⅛ in. diameter behind the shoulder. With another square turret cutter, turn the 1⅞ in. and 1 3-16 in. diameter. The two turrets finishing their work simultaneously.

2nd Operation:—Turn the ¾ in. diameter.
3rd Operation:—Center Shaft.
4th Operation:—Turn the 1 in. tapered diameter with taper attachment and nick with square turrent cutter.
5th Operation:—Thread ¾ in. diameter.
6th Operation:—Cut off.

Warner & Swasey turret lathes will mean sure profits to you. Send blueprints for an analysis like the shaft job here.

THE WARNER & SWASEY COMPANY

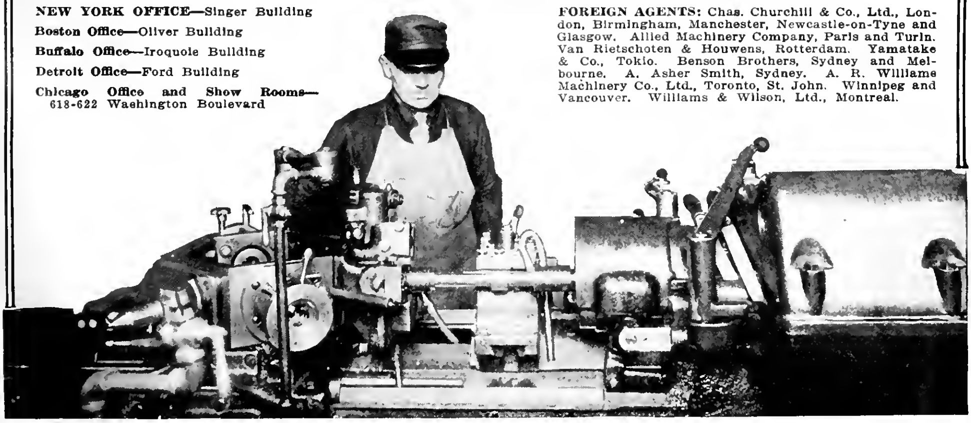
NEW YORK OFFICE—Singer Building
Boston Office—Oliver Building
Buffalo Office—Iroquois Building
Detroit Office—Ford Building
Chicago Office and Show Rooms—618-622 Washington Boulevard

FOREIGN AGENTS: Chas. Churchill & Co., Ltd., London, Birmingham, Manchester, Newcastle-on-Tyne and Glasgow. Allied Machinery Company, Paris and Turin. Van Rietschoten & Houwens, Rotterdam. Yamatake & Co., Tokio. Benson Brothers, Sydney and Melbourne. A. Asher Smith, Sydney. A. R. Williams Machinery Co., Ltd., Toronto, St. John. Winnipeg and Vancouver. Williams & Wilson, Ltd., Montreal.



unusually high tensile strength and shock resisting qualities.

Iron, Carbon, and Phosphorus, J. E. Stead. Iron & Steel Inst. of Can., vol. 1, no. 8, Sept. 1918, pp. 323-333, 23 figs. Effect of introducing carbon, by cementation, into homogeneous solid solutions of iron and phosphorus; temperature ranges in which free phosphide of iron passes in and out of solid solution in iron. Before Iron & Steel Inst.

Non-Metallic Inclusions: Their Constitution and Occurrence in Steel, Andrew McCance. Iron & Steel of Can., vol. 1, no. 9, Oct. 1918, pp. 374-388, 35 figs. Experimental study of part played by inclusions in developing weaknesses and producing defects in steel products. (To be concluded.)

Note on Certain Colored Interference Bonds and the Colors of Tempered Steel, A. Mallock. Proc. Roy Soc., vol. 91, no. A664, Aug. 1, 1918, pp. 561-566, 2 figs. Scientific explanation of interference phenomena observed with two sheets of gauze when their distance is gradually altered.

The Influence of some Elements on the Tenacity of Basic Steel, with a new Formula for Calculating the Maximum Load from the Composition, Andrew McWilliam. Iron & Steel Inst., advance copy, paper 13, Sept. 12-13, 1918, 13 pp., 3 figs. Formula for sections that would give results near to those obtained on 1-in. round bars normalized, table showing effect of carbon between 0.1 and 0.75, and results of application of formula to certain series of steel.

Tantiron

Tantiron; Am. Acid Resisting Ferro-Silicon Alloy. Can. Machy., vol. 20, no. 17, Oct. 24, 1918, pp. 477-480, 8 figs. Properties, limitations, corrosion, molding and specialties. (See also Acid Resisting Irons.)

Testing

The Applicability of Electrical Resistance Measurements for the Investigation of Iron and Steel (Om användbarheten av elektriska motstandstmätningar för undersökning av järn och stal), B. D. Enlund. Jern-Kontorets Annaler, Nos. 3-4, 1918, pp. 165-221, 46 figs.

The Magnetic Analysis as a Means of Studying the Structure of Iron Alloys, Kôtaro Honda. Iron & Steel Inst., advance copy, paper 9, Sept. 12-13, 1918, 43 pp., 46 figs. Method based on following experimental facts: (1) the intensity of magnetization of simple homogeneous ferro-magnetic substances decreases at first slowly and subsequently more and more rapidly as temperature increases, and it vanishes at the critical temperature; (2) the critical temperature of a ferro-magnetic element or compound is a characteristic of substance independent of external conditions; (3) the magnetic susceptibility of a substance is abruptly changed when it undergoes an allotropic transformation.

Tuyeres

A Few Notes on Bosh Tuyeres, J. Hollings. Iron & Steel Inst., advance copy, paper 8, Sept. 12-13, 1918, 9 pp., 2 figs. Account of circumstances which led to adoption by author of bosh tuyeres, in 48-ft. furnace at Brymbo.

See also Railroad Engineering, Steam (Rails); Corrosion (Iron).

TERMINALS

Chicago

The Pennsylvania's New Goods Depot at Chicago. Ry. Gaz., vol. 29, no. 12, Sept. 20, 1918, pp. 304-307, 4 figs. Layout of tracks, general plans of floors and cross-sections.

Large Cities

Urges Study of Unit Operation of Railroad Terminals in Large Cities. Eng. News-Rec., vol. 81, no. 14, Oct. 3, 1918, pp. 615-619. Yards and Terminals Committee, Railway Engineering Assn., presents a special report recommending investigation by representative committees of possibilities of coördinating existing facilities.

St. Paul

Engineering at the St. Paul Passenger Terminal. Ry. Rev., vol. 63, no. 17, Oct. 26, 1918, pp. 595-597, 1 fig. New station; elevated tracks eliminating street crossings at grade; coach yard and locomotive terminal.

Toronto

Toronto Union Station an Imposing Structure. Can. Engr., vol. 35, no. 15, Oct. 10, 1918, pp. 319-321, 6 figs. Brief description of chief sub-contracts.

See also Lighting (Factory Lighting).

TESTING AND MEASUREMENT

Cells, Normal

Report on the Weston Normal Cells Exchanged with the Bureau of Standards and the National Physical Laboratory, Jûichi Obata. Department of Communications, Tokyo, Japan, Researches of the Electrotechnical Laboratory, no. 70, May 1918, 11 pp., 1 fig. Method of preparation of cell; three series of comparisons; variation in electromotive force of cell after transportation.

Dynamometers

A 900-Hp. Dynamometer Installation. Automotive Ind., vol. 39, no. 11, Sept. 12, 1918, pp. 449-451, 5 figs. Features relating to water cooling, exhaust disposal and dynamometer tests of mammoth engines in test house of Duesenberg Motors Corp. Also in Aviation, vol. 5, no. 6, Oct. 15, 1918, p. 371, 4 figs.

Gases, Temperature

Measuring the Temperature of Gases in Boiler Settings. H. Kreisinger and J. F. Barkley. Department of the Interior, Bureau of Mines, bul. 145, 72 pp., 31 figs. Discussion of various sources of error; manipulation of the potentiometer; list of publications on the utilization of coal and lignite.

Hardness

A New Method of Obtaining Brinell Hardness, J. G. Ayers. Automotive Ind., vol. 39, no. 11, Sept. 12, 1918, p. 457, 2 figs. Impact substituted for steady pressure to reduce time required for applying test.

Report on Hardness Testing: Relation between Ball Hardness and Scleroscope Hardness, A. F. Shore. Iron & Steel Inst., advance copy, paper 15, Sept. 12-13, 1918, 19 pp., 11 figs. Report of tests performed on a variety of metals both ferrous and non-ferrous, with different states of heat-treatment.

Hygrometry

Hygrometry in terms of the Weight of a Film of Gelatine, C. Barns. Science, vol. 48, no. 1241, Oct. 11, 1918, pp. 374-376, 2 figs. Adaptation of form of horizontal torsion balance used by author in measuring absolute viscosity of steel to indications of absorption of atmospheric vapors.

Insulation Resistance

Note on Measuring a Metallic or Insulation Resistance by the Voltmeter Method (Note sur la mesure d'une résistance (métallique ou d'isolement) par la méthode du voltmètre), Puget. Revue Générale de l'Electricité, vol. 4, no. 10, Sept. 7, 1918, p. 298, 2 figs. Indicates two methods to simplify for workingmen calculations involved in application of usual formula $X = R\,\frac{E - v}{u}$, where R is voltmeter resistance, E deviation connecting battery to voltmeter and u deviation with resistance in circuit.

Lead Testing

Lead Testing Machine. Can. Machy., vol. 20, no. 17, Oct. 24, 1918, pp. 484-485, 2 figs. Device consists of cast-iron bed machined all over with two parallel dovetail bearings on top.

Manometers

The Krell Manometer, A. A. Merrill. Aviation, vol. 5, no. 7, Nov. 1, 1918, pp. 421-422, 2 figs. Modification of air-laboratory U-type, in which one branch of U is a glass tube set at a small angle and other branch is a large tank.

Metric System

The International Bureau of Weights and Measures. Sci. Am. Supp., vol. 86, no. 2229, Sept. 21, 1918, pp. 186-187. Motives for creation and special features of metric system. From La Nature.

Pyrometers

The Types and Industrial Uses of Pyrometers. Can. Foundryman, vol. 9, no. 8, Aug. 1918, pp. 179-182, 3 figs. Classification into "contact" and "distant" classes; variation in indications; suitability of different types; location; details of electric circuit; radiation pyrometers.

Sand

Progress Report of Committee on Mechanical Analysis of Sands. Can. Engr., vol. 35, no. 18, Oct. 31, 1918, pp. 387-390. Specifications for standard sieves; methods of making mechanical analysis. From Report of Committee by Am. Water Works Assn.

Shell Steel

Physical Tests of Rolled Shell Steel, James J. Mahon. Iron Age, vol. 102, no. 18, Oct. 31, 1918, pp. 1082-1083, 2 figs. Explanation of frequent results at variance with chemical analysis; excessive precipitation of ferrite corrected by heat treatment.

Testing Machine, Tension and Compression

A Novel Tension and Compression Testing Instrument, Frank C. Perkins. Can. Machy., vol. 20, no. 14, Oct. 3, 1918, pp. 391-392, 6 figs. Device, applicable to wide range of specimen sizes, consists of two adjustable frames, each carrying two screws bearing on gage marks on specimen.

Thread Measurement

Projection Lantern for Thread Measurement, H. L. Van Keuren and E. C. Griess. Am. Mach., vol. 49, no. 18, Oct. 31, 1918, pp. 805-811, 10 figs. Describing an apparatus developed by the Bureau of Standards.

Voltameters

The Richards Form Silver Voltameters, Jûichi Obata. Department of Communications, Tokyo, Japan, Researches of the Electrotechnical Laboratory, no. 71, July 1918, 29 pp., 1 fig. Experimental investigation of the anode compilations in the silver voltameter and determination of voltage of Weston normal cell with Richards form silver voltameter.

See also Brick, Clay and Stone (Abrasion Test); Chemical Technology (Explosives); Hydraulic Engineering (Water Measurements); Lighting (Photometers); Metallurgy (Hardness of Metals); Refractories (Tests); Steel and Iron (Pyrometry); Steel and Iron (Testing).

THERMODYNAMICS

Heat-Transmission Tables

New Heat Transmission Tables, William R. Jones, Heat. & Vent. Mag., vol. 15, no. 10, Oct. 1918, pp. 36-41. Compilation in tabular form of factors given by leading authorities covering latest types of construction.

TIMBER

See Wood.

TRANSPORTATION

Farm Transport

Cheap Transport for Farmers and Rural Industries, Frank Dutton. South African Jl. of Industry, vol. 1, no. 12, Aug. 1918, pp. 1089-1105, 8 figs. Discussion of problem and description of possible solution by means of portable rail tracks for tractors.

Yard Transfer

Operating Methods of Transfer Railroads. Ry. Rev., vol. 63, no. 14, Oct. 5, 1918, pp. 490-493. Analysis of existing conditions and suggestions for improvement to meet demands of increased traffic. From paper by E. H. Lee contributed to preliminary report of Committee on Yards and Terminals, Am. Ry. Eng. Assn., Sept. 1918.

WOOD

Aeroplane Woods

Defects in Airplane Woods, Samuel J. Record. Sci. Am., vol. 119, no. 11, Sept. 14, 1918, p. 212, 5 figs. Method of judging quality of timber.

House Finish

The Uses of Wood (VI), Hu. Maxwell. Am. Forestry, vol. 24, no. 298, Oct. 1918, pp. 593-602, 16 figs. Its employment as house finish.

Kilns

Observation on Kiln Practice, N. S. Potter. Cement & Eng. News, vol. 30, no. 8, Aug. 1918, pp. 35-36. Suggestions as to the points to investigate in connection with raw material, kiln, coal, air, burner, draft and discharged gases, in order to secure efficient operation.

See also Engineering Materials (Precast Concrete Lumber); Fuel and Firing (Wood Burning).

WOOD-WORKING MACHINERY

Tie-Dressing Machine

Machine Dress Railroad Ties Before Treatment. Eng. News-Rec., vol. 81, no. 15, Oct. 10, 1918, 2 figs. Santa Fé stationary and portable plants that saw, adze, bore and brand ties in one continuous operation.
